Graph Theory Part Two

Outline for Today

- *Walks, Paths, and Reachability*
	- Walking around a graph.
- *Application: Local Area Networks*
	- Graphs meet computer networking.
- *Trees*
	- A fundamental class of graphs.

Recap from Last Time

Graphs and Digraphs

- A *graph* is a pair $G = (V, E)$ of a set of nodes *V* and set of edges *E*.
	- Nodes can be anything.
	- Edges are *unordered pairs* of nodes. If $\{u, v\} \in E$, then there's an edge from *u* to *v*.
- A *digraph* is a pair $G = (V, E)$ of a set of nodes *V* and set of directed edges *E*.
	- Each edge is represented as the ordered pair (*u*, *v*) indicating an edge from *u* to *v*.

Two nodes in an undirected graph are called *adjacent* if there is an edge between them.

Using our Formalisms

- Let $G = (V, E)$ be an (undirected) graph.
- Intuitively, two nodes are adjacent if they're linked by an edge.
- Formally speaking, we say that two nodes *u*, *v* ∈ *V* are *adjacent* if we have $\{u, v\}$ ∈ *E*.
- There isn't an analogous notion for directed graphs. We usually just say "there's an edge from *u* to *v*" as a way of reading $(u, v) \in E$ aloud.

New Stuff!

Walks, Paths, and Reachability

A *walk* in a graph $G = (V, E)$ is a sequence of one or more nodes *v*¹, *v*², *v*³, …, *v*ⁿ such that any two consecutive nodes in the sequence are adjacent.

The *length* of the walk v_1 , ..., v_n is $n-1$.

A *closed walk* in a graph is a walk from a node back to itself. (By convention, a closed walk cannot have length zero.)

A *path* in a graph is walk that does not repeat any nodes.

A *cycle* in a graph is a closed walk that does not repeat any nodes or edges except the first/last node.

A \boldsymbol{walk} in a graph $G = (V, E)$ is a sequence of one or more nodes *v*₁, *v*₂, *v*₃, …, *vₙ* such that any two consecutive nodes in the sequence are adjacent.

A *path* in a graph is walk that does not repeat any nodes.

A node *v* is *reachable* from a node *u* when there is a path from *u* to *v* .

A graph *G* is called *connected* when all pairs of distinct nodes in *G* are reachable.

A *connected component* (or *CC*) of *G* is a set consisting of a node and every node reachable from it.

Fun Facts

- Here's a collection of useful facts about graphs that you can take as a given.
	- **Theorem:** If $G = (V, E)$ is a (directed or undirected) graph and *u*, v ∈ *V*, then there is a path from *u* to *v* if and only if there's a walk from *u* to *v*.
	- *Theorem:* If *G* is an undirected graph and *C* is a cycle in *G*, then *C*'s length is at least three and *C* contains at least three nodes.
	- **Theorem:** If $G = (V, E)$ is an undirected graph, then every node in V belongs to exactly one connected component of *G*.
	- **Theorem:** If $G = (V, E)$ is a (directed or undirected) graph and u , y_0 , *y*₁, …, *yₘ*, *v* is a walk from *u* to *v* and *v*, *z*₀, *z*₁, …, *zₙ*, *x* is a walk from *v* to *x*, then *u*, *y*^o, *y*¹, …, *y*^m, *v*, *z*⁰, *z*₁, …, *z*_n, *x* is a walk from *u* to *x*.

Time-Out for Announcements!

Problem Set Two Graded

Midterm Exam Logistics

- Our first midterm exam is next *Monday, October 21st* from *7:00PM – 10:00PM*.
	- Seat assignments will be available online tonight.
- You're responsible for Lectures 00 05 and topics covered in PS1 – PS2. Later lectures (functions forward) and problem sets (PS3 onward) won't be tested here. Exam problems may build on the written or coding components from the problem sets.
- The exam is closed-book, closed-computer, and limitednote. You can bring a double-sided, $8.5'' \times 11''$ sheet of notes with you to the exam, decorated however you'd like.
- Students with alternate exam arrangements: you should hear from us by the end of the day with details. If you don't, contact us ASAP.

Preparing for the Exam

- We have an extra credit pre-midterm reflection exercise you can use to prepare for the exam. It's linked on Ed.
- Kaia is holding a review session this Friday at 3:00PM, location TBA.
- Make sure to *review your feedback* on PS1 and PS2.
	- "Make new mistakes."
	- Come talk to us if you have questions!
- There's a huge bank of practice problems up on the course website.
- Best of luck **you can do this!**

Participation Opt-Out

- By default, all on-campus students have 5% of their grade allocated from lecture attendance and participation.
- If you are an on-campus student and want to opt out, shifting that 5% onto your final exam, fill out the opt-out form on Ed by this Friday.

Back to CS103!

Application: *Local Area Networks*

The Internet and LANs

- The internet consists of several separate *local area networks* (*LANs*) that are "internetworked" together.
- Local area networks cover small areas a single hallway in a dorm, an office building, a college campus, etc.
- The internet then links those smaller LANs into one giant network where everyone can talk to everyone.
- **Focus for today:** How do messages flow through a LAN?

Message Movement

- When a computer receives a message, it repeats that message on all its links except the one it received the message on.
- The computers don't inspect the message contents or try to be clever – it's purely "came in on link *X*, goes out on all links but *X*."

Broadcast Storms

- A **broadcast storm** occurs when there's a cycle in the network graph.
- A single message can repeat forever, or exponentially amplify until the network fails.
- *Solution:* Don't let the network graph have any cycles.
- A graph $G = (V, E)$ is called *acyclic* if it has no cycles.

You have a collection of computers that need to be wired up into a LAN. How should you choose the shape of the network?

Minimally Connected

(Connected, but deleting any edge disconnects its endpoints.)

Connected, Acyclic

If *any* of these conditions hold, then *all* of these conditions hold.

A graph with any of these properties is called a *tree*.

Maximally Acyclic

(Acyclic, but adding any missing edge creates a cycle.)

Theorem: Let $T = (V, E)$ be a graph. If T is connected and acyclic, then *T* is maximally acyclic.

Proof: Assume *T* is connected and has no cycles. We need to prove that *T* is maximally acyclic. We already know that *T* is acyclic. So choose distinct nodes $x, y \in V$ where $\{x, y\} \notin E$; we'll prove adding $\{x, y\}$ to *E* closes a cycle.

Because *T* is connected, there is a path *x*, …, *y* from *x* to *y* in *T*. Now add {*x*, *y*} to *E*. Then we can form the closed walk *x*, …, *y*, *x*. We claim that this is a cycle. To see this, note the following:

- No node is repeated except the start/end node *x*: nodes *x*, …, *y* are all distinct because *x*, …, *y* is a path.
- No edge appears twice: none of the edges used in *x*, …, *y* are repeated (*x*, …, *y* is a path). Furthermore, the edge $\{x, y\}$ isn't repeated since the path $x, ..., y$ was formed before {*x*, *y*} was added to *E*.

Thus adding {*x*, *y*} to *E* closes a cycle, as required. ■

Theorem: Let $T = (V, E)$ be a graph. If T is minimally connected, then *T* is connected and acyclic.

Proof: Assume *T* is minimally connected. We need to show that *T* is connected and acyclic. Since *T* is minimally connected, it's connected, and so we just need to show that *T* is acyclic.

Suppose for the sake of contradiction that *T* contains a cycle *x*, …, *y*, *x*. Note in particular that this means *x*, …, *y* is a path in *T* and that this path does not use the edge {*x*, *y*}.

Since *T* is minimally connected, deleting the edge {*x*, *y*} from *T* makes *y* not reachable from *x*. However, we said earlier that *x*, …, *y* is a path from *x* to *y* in *T* that does not use {*x*, *y*}, so *x* and *y* remain reachable after deleting {*x*, *y*}.

We have reached a contradiction, so our assumption was wrong and *T* is acyclic. ■

Check the appendix for the other two steps of the proof.

More to Explore

- Actual local area networks allow for cycles. They use something called the *spanning tree protocol* (*STP*) to selectively disable links to form a tree.
- Routing through the full internet not just within a LAN – is a fascinating topic in its own right.
- Take CS144 (networking) for details!

Recap from Today

- *Walks* and *closed walks* represent ways of moving around a graph. *Paths* and *cycles* are "redundancy-free" walks and cycles.
- *Trees* are graphs that are connected and acyclic. They're also minimally-connected graphs and maximally-acyclic graphs.
- Trees have applications throughout CS, including networking.

Next Time

- *The Pigeonhole Principle*
	- A simple, powerful, versatile theorem.
- *Graph Theory Party Tricks*
	- Applying math to graphs of people!
- *A Little Movie Puzzle*
	- Who watched what?

Minimally Connected

(Connected, but deleting any edge disconnects its endpoints.)

Maximally Acyclic

(Acyclic, but adding any missing edge creates a cycle.)

Theorem: Let $T = (V, E)$ be a graph. If T is maximally acyclic, then *T* is minimally connected.

Proof: Assume *T* is maximally acyclic. We need to prove that *T* is minimally connected. To do so, we first prove *T* is connected. Pick any $x, y \in V$ where $x \neq y$; we'll show there's a path from *x* to *y*. Consider two cases:

Case 1: $\{x, y\} \in E$. Then *x*, *y* is a path from *x* to *y*.

Case 2: $\{x, y\} \notin E$. Imagine adding $\{x, y\}$ to *E*. Since *T* is maximally acyclic, this closes a cycle *x*, …, *y*, *x* passing through $\{x, y\}$. Then x , ..., y is a path in T from x to y .

In either case, we have a path from *x* to *y*, as needed.

Next, suppose for the sake of contradiction that there is an edge $\{x, y\} \in E$ where *T* remains connected after deleting {*x*, *y*}. This means that there is a path *x*, …, *y* in *T* after removing $\{x, y\}$. By adding $\{x, y\}$ to the end of the path, we form a cycle *x*, …, *y*, *x* in *T*. This is impossible because *T* is acyclic. We've reached a contradiction, so our assumption was wrong and *T* is minimally connected. ■
