CME 192: Introduction to MATLAB
Lecture 2

Stanford University

January 17, 2019

Outline

Review

Lecture 1

- Variables
- Operators
- Built-in functions
- Arrays: vectors and matrices
- Strings
- Cell Arrays
- Using documentation

Outline

Scripts

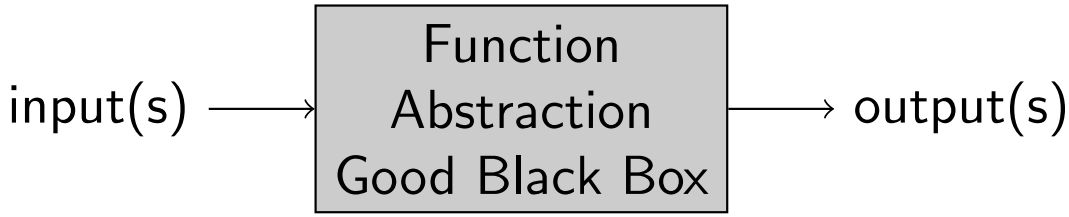
`script.m`

```
1 % most common sum of two die
2 % randi(<rand 1 to n>, <rows>, <
      cols>)
3 N = 10^5;
4 dice1 = randi(6, 1, N);
5 dice2 = randi(6, 1, N);
6
7 % result
8 mode(dice1 + dice2)
```

7

- a series of MATLAB commands
- equivalent to command line history
- good for quick prototyping
- `.m` extension
- no input arguments, no outputs
- use workspace variables (global)

What is a function?



- important concept
- allows for abstraction
- abstraction allows for complexity
- abstraction allows for code sharing

```
function [<out1>, <out2>, ...] = <name>(<arg1>, <arg2>, ...)
  <statement1>
  <statement2>
  <statement3>
   ...
end
```

Functions

common_sum.m

```
1 function s = common_sum(N)
2   dice1 = randi(6, 1, N);
3   dice2 = randi(6, 1, N);
4
5   % suppressed
6   s = mode(dice1 + dice2);
7 end
```

```
>> common_sum(10^5)
ans = 7
```

- takes inputs, produces outputs
- can be a program
- good for abstraction
- `.m` extension
- same name as the file
- doesn't create workspace variables (global)

Multiple Output Arguments Functions

cplx2mag_ang.m

```
1 function [mag, ang] =
      cplx2mag_ang(c)
2   mag = abs(c);
3
4   % in computers always radians
5   ang = angle(c);
6 end
```

```
>> [m, a] = cplx2mag_ang(4 + 2i)
m =  4.4721
a =  0.46365
>> % discard one output with ~
>> [~, a] = cplx2mag_ang(4 + 2i)
a =  0.46365
>> [m, ~] = cplx2mag_ang(4 + 2i)
m =  4.4721
```

- useful when computational effort can be combined
- typically better to use separate functions
- don't overuse, 4 output arguments is probably too many

Helper Functions

mag_ratio.m

```
1 % magnitude ratio of two vectors
2 function r = mag_ratio(v1, v2)
3   r = mag(v1) / mag(v2);
4 end
5
6 % magnitude of a 2D vector
7 function m = mag(v)
8   m = sqrt(v(1)^2 + v(2)^2);
9 end
```

- place after the main function
- not available from command line
- easily reuse code
- form logical operations into functions
- improve readability

Anonymous Functions

```
% find for which x, f(x) = x *
    cos(x) = 4
f = @(x) x * cos(x) - 4;
% fzero(<fn>, <guess>), finds
    function zero
fzero(f, 3.0)
```

```
>> script
ans = 5.5224
```

```
% function generator
function fn = add_x(x)
  fn = @(z) z + x;
end
```

```
>> add2 = add_x(2);
>> add2(4)
ans = 6
```

Format

```
<fn_name> = @(<arg1>, <
    arg2>, ...) <output>
```

- necessary for functions operating on functions (ODE, zero finding, etc.)
- suited for simple applications
- useful for working in the command line

Commenting

```
1 % use % symbol for comments
2
3 %% for section headings
4
5 %{
6 use %{ for blocks of comments
7 close with
8 %}
```

- comment non-trivial code
- do not comment trivial code

Output Printing

```
1  x = 2;
2  x
3  disp(x);
4  % fprintf(<string>, <var1>, <var2>, ...)
5  % formats:
6  % integer - %d, real - %f, character - %c, string - %s
7  fprintf('x is %f \n', x);
8  fprintf('x is %d \n', x);
9  % \n is the newline character
10 fprintf('x is %d', x);
11 fprintf('x is %d', x);
```

```
x =
   2
2
x is 2.0000
x is 2
x is 2x is 2
```

Scripts & Functions

	Scripts	Functions
`.m` extensions	✓	✓
inputs, outputs		✓
workspace variables	✓	
same name as file	n/a	✓
can be a program	✓	✓
helper functions in same file		✓
preferred		✓

Outline

Relational and Logical Operators

Relational operators

`A == B`	equality, element wise
`A ~= B`	inequality, element wise
`A > B`	greater than, element wise
`A < B`	less than, element wise
`A >= B`	greater equal than, element wise
`A <= B`	less equal than, element wise

Logical operators

`A & B`	and, both true, element wise
`A | B`	or, either or both true, element wise
`~A`	not, true if false, false if true, element wise
`xor(A, B)`	exclusive or, only true if only one true, element wise

Other

`any(A)`	is at least one element true
`all(A)`	are all elements true
`strcmp(A, B)`	compare two strings

Conditional `if` statements

my_abs.m

```
1 % absolute value
2 function x = my_abs(x)
3   if x >= 0.0
4     x = x;
5   else
6     x = -x;
7   end
8 end
```

Format

```
1 if <condition>
2   <statement(s)>
3 elseif <other condition>
4   <statement(s)>
5 else
6   <statement(s)>
7 end
```

Conditional `switch` statements

pos_neg_abs.m

```
1  % absolute value
2  function x = pos_neg_abs(x,
       pos_neg)
3    switch pos_neg
4      case 'pos'
5        x = my_abs(x);
6      case 'neg'
7        x = -my_abs(x);
8      otherwise
9        error('Function
       accepts only ''neg'' or
        ''pos''');
10   end
11 end
```

Format

```
1 switch <cond_var>
2   case <condition1>
3     <statement(s)>
4   case <condition2>
5     <statement(s)>
6   otherwise
7     <statement(s)>
8 end
```

```
>> pos_neg_abs(-17, 'pos')
ans = 17
>> pos_neg_abs(5, 'neg')
ans = -5
```

While Loop

play_dice.m

```
1 % play dice, lose on 1
2 function play_dice(x)
3   last_throw = 6;
4   while last_throw ~= 1
5     last_throw = randi(6);
6   end
7 end
```

Format

```
1 while <condition>
2   <statement(s)>
3 end
```

For Loop

count_positive.m

```
1  % count positive elements
       in an array
2  function c = count_positive
       (v)
3    c = 0;
4    for i = 1:length(v)
5      if v(i) >= 0.0
6        c = c + 1;
7      end
8    end
9    % or
10   c = 0;
11   for el = v
12     if el >= 0.0
13       c = c + 1;
14     end
15   end
16 end
```

Format

```
1 for <it> = <start>:<end>
2   <statement(s)>
3 end
```

or

```
1 for <it> = <container>
2   <statement(s)>
3 end
```

Nested For Loop

all_negative.m

```
1 % return matrix with all negative elements
2 function M = all_negative(M)
3   for i = 1:size(M, 1)
4     for j = 1:size(M, 2)
5       M(i, j) = -abs(M(i, j));
6     end
7   end
8 end
```

break and continue

infinite.m

```
1  function infinite()
2    r = 6;
3    while 1 % finishes
4      r = randi(10^3);
5      if r == 1
6        break
7      end
8    end
9
10   while 1 % never finishes
11     r = randi(10^3);
12     if r == 1
13       continue
14     end
15     if r == 1
16       break
17     end
18   end
19 end
```

- `break` to break out of the loop
- `continue` to jump to the next iteration
- Ctrl+C interrupts execution

Outline

Reading Erros

remember_el_wise.m

```
1 function remember_el_wise()
2   A = rand(4, 4);
3   v = ones(1, 4);
4
5   A2 = A^2;
6   res = A2 * v;
7
8   disp(res);
9 end
```

- MATLAB executes line by line → pay attention to line number
- MATLAB has descriptive errors → try to read the error message

```
>> remember_el_wise
error: remember_el_wise: operator *:
nonconformant arguments (op1 is 4x4, op2 is 1x4)
error: called from
    remember_el_wise at line 6 column 7
```

Log (print) execution

mand.m

```
1 % iterate Mandelbrot function
2 function z = mand(c)
3   f = @(z) z^2 + c;
4   z = 1e10;
5   for i = 1:5
6     z = f(z) % unsuppressed
7   end
8 end
```

```
>> mand(4 + 4i)
z =   1.0000e+20 + 4.0000e+00i
z =   1.0000e+40 + 8.0000e+20i
z =   1.0000e+80 + 1.6000e+61i
z =   1.0000e+160 + 3.2000e+141i
z = Inf - NaNi
ans = Inf - NaNi
```

- good for quick debugging
- gives insight into execution
- practically all other debugging tactics are better

Breakpoints

- Universal programming concept
- Stops program execution, allows to examine state of memory (variables)
- Available in virtually any programming language
- MATLAB (and Octave) GUI programs have good support for them, click line number
- Program execution resumed manually

Reason Through Execution

- Read the code line by line
- See if you can spot easy errors
- Reconcile program behavior with text on the screen

Rubber Duck Debugging

- Useful when all other techniques have failed
- Sit down and explain your program to a rubber duck (or a friend)
