Haplotype Frequencies

		Locus B		Totals
		B	b	
Locus A	A	p_{AB}	p_{Ab}	p_A
	a	p_{aB}	p_{ab}	p_a
Totals		p_B	p_b	1.0

Fill out this table.

X11 is number of times that haplotype is seen.

	2818 C	**2818 T**	
3027 T	X11	X21	# 3027 T alleles
3027 C	X12	x22	#3027 C alleles
	# 2818 C Allele	# 2818 T allele	

	2818 C	2818 T	
3027 T	125/146	2/146	127/146 T alleles
3027 C	9/146	10/146	19/146 C alleles
	134/146 C Allele	12/146 T allele	

Convert to fractions

	2818 C	**2818 T**	
3027 T	.86	.013	.87 T alleles
3027 C	.061	.068	.13 C alleles
	.92 C Allele	.08 T allele	

Disequilibrium Coefficient D_{AB}

$$D_{AB} = p_{AB} - p_A p_B$$

$$p_{AB} = p_A p_B + D_{AB}$$

$$p_{Ab} = p_A p_b - D_{AB}$$

$$p_{aB} = p_a p_B - D_{AB}$$

$$p_{ab} = p_a p_b + D_{AB}$$

Calculate D_{AB}

$$D_{AB} = P_{AB} - P_A P_B$$
$$= .86 - (.87)(.92)$$
$$= .86 - .80$$
$$= .06$$

D_{AB} is hard to interpret

- Sign is arbitrary …
  - A common convention is to set A, B to be the common allele and a, b to be the rare allele
- Range depends on allele frequencies
  - Hard to compare between markers

R – correlation coefficient

$$R = \frac{D_{AB}}{SQR(P_A \times P_a \times P_B \times P_b)}$$

Calculate R

$R = D_{AB} / SQR(P_A P_a P_B P_b)$

$= .06 / SQR(.87 * .13 * .92 * .08)$

$= .06 / SQR(7.2 \times 10^{-3})$

$= .06 / .085 = .706$

$R^2 = .497$

More on r^2

- $r^2 = 1$ implies the markers provide exactly the same information
- The measure preferred by population geneticists
- Measures loss in efficiency when marker A is replaced with marker B in an association study
  - With some simplifying assumptions (e.g. see Pritchard and Przeworski, 2001)

additive: GG > GT > TT

Do linear regression 3 genotype x 2 groups

How different is this SNP in the cases versus the controls?

Allelic odds ratio: ratio of the allele ratios in the cases divided by the allele ratios in the controls

Cancer .57 G/.43 T = 1.32

Control .49 G/ .51T = 0.96

Allelic Odds Ratio = 1.32/0.96 = 1.37

How different is this SNP in the cases versus everyone?

Allelic odds ratio*: ratio of the allele ratios in the cases divided by the allele ratio in the entire population

(need allele ratio from entire population to do this)

Likelihood ratio: What is the likelihood of seeing a genotype given the disease compared to the likelihood of seeing the genotype given no disease?

(need data from entire population to do this. We can do this in the class GWAS. For cancer vs controls, the two groups were separate and so we do not know the genotype frequencies of the population as a whole.)

Increased Risk: What is the likelihood of seeing a trait given a genotype compared to overall likelihood of seeing the trait in the population?

(need data from entire population to do this. We can do this in the class GWAS. For cancer vs controls, the two groups were separate and so we do not know the genotype frequencies of the population as a whole.)

Multiple hypothesis testing

"Of the 547,647 polymorphic tag SNPs, 27,673 showed an association with disease at $P < .05$."

- $P = .05$ means that there is a 5% chance for this to occur randomly.
- If you try 100 times, you will get about 5 hits.
- If you try 547,647 times, you should expect $547,647 \times .05 = 27,382$ hits.
- So 27,673 (observed) is about the same as one would randomly expect.

Multiple hypothesis testing

"Of the 547,647 polymorphic tag SNPs, 27,673 showed an association with disease at $P < .05$."

- Here, have 547,647 SNPs = # hypotheses
- False discover rate = q = p x # hypotheses. This is called the Bonferroni correction.
- Want q = .05. This means a positive SNP has a .05 likelihood of rising by chance.
- At q = .05, p = .05 / 547,647 = $.91 \times 10^{-7}$
- This is the p value cutoff used in the paper.

Multiple hypothesis testing

"Of the 547,647 polymorphic tag SNPs, 27,673 showed an association with disease at $P < .05$."

- The Bonferroni correction is too conservative. It assumes that all of the tests are independent.
- But the SNPs are linked in haplotype blocks, so there really are less independent hypotheses than SNPs.
- Another way to correct is to permute the data many times, and see how many times a SNP comes up in the permuted data at a particular threshold.

SNPedia

Summarize the trait
Summarize the study
- How large was the cohort?
- How strong was the p-value?
- What was the OR, likelihood ratio or increased risk?

Which population?
What is known about the SNP?
- Associated genes?
- Protein coding?
- Allele frequency?

Does knowledge of the SNP affect diagnosis or treatment?

Class GWAS

Go to genotation.stanford.edu
Go to “traits”, then “GWAS”
Look up your SNPs
Fill out the table
Submit information

Class GWAS

Class should split into ~10 groups
Each group should calculate association of all 5 SNPs with one trait.
Do a chi-squared test and write down the p value.
We will make a table from the class results

Class GWAS

Which SNP is best associated with which trait?
Is this significant? What should be the significance cut off?
Are there other significant associations?
What might cause the other significant associations?

Class GWAS

Split into groups of 4-5
Each group should select on trait/SNP
Calculate:

- allelic odds ratio
- likelihood ratio
