Project Proposals for MS&E 448  $\,$ 

Spring Quarter 2020 Dr. Lisa Borland

# 1 Build a High Frequency Strategy

#### Description

The goal of this project is to design and implement a trading strategy based on limit order book data, i.e. high frequency stocks data, that exploits the specific structure of such datasets.

#### Initial questions

- What is a good time scale to consider: tick-by-tick or a larger time-scale (for example, can an integrated order book profile predict anything over longer horizons)?
- Use machine learning techniques or impose a fundamental relationship
- Discuss and analyze execution tactics (eg if you are aggressing, can you really get that price? How much slippage do you expect? Adverse selection?)
- Given the nature of your alpha signal, and how you expect the price to move immediately after entering an order, what is the best execution strategy to optimize the probability of fill in such a way that you minimize market impact and avoid adverse selection?
- If you can make money getting the mid price, but lose if you have to pay the spread, can you get around this by executing cleverly?
- Given multiple potential counterparty venues with different liquidity profiles, response times, rejection rates, spreads, how do you optimally route your orders?

#### Data and coding environment

Students will have access to MayStreet limit order book data and high frequency simulator.

### 2 Build a statistical arbitrage strategy

#### Description

The goal of this project is to design and implement a statistical arbitrage trading strategy. This implies identifying pairs or groups of stocks that are expected to behave similarly and use this to exploit their prices differences.

#### Initial questions

- Do you want to consider pairs of stocks or create clusters of similar stocks?
- How can you find similar stocks?
- What technique can you use to predict residuals returns: O-U process or other statistical techniques?
- How can you use your signal to create a portfolio that optimize for risk, transaction costs, liquidity etc?

#### Data and coding environment

Refer to the Guide to Financial Data in the Data section of the website. Once you will have designed a strategy, you can simulate its performance in a finance simulator such as Quantopian or cvxportfolio.

### 3 Build an index arbitrage strategy

#### Description

The goal of this project is to design and implement an index arbitrage trading strategy which is a variant of statistical arbitrage. Index arbitrage can be done in various different ways. One way is to identifying spread between spot prices of stocks constituting of an index and the related index futures contract. Another way, is to measure within an index, the degree of reactivity of each stock to the market impact. Spread between leaders and laggers can then be exploited.

#### Data and coding environment

Refer to the Guide to Financial Data in the Data section of the website. Once you will have designed a strategy, you can simulate its performance in a finance simulator such as Quantopian or cvxportfolio. Students can also have access to MayStreet limit order book data and high frequency simulator.

### 4 Build an volume-based strategy

#### Description

The goal of this project is to design and implement a volume-based strategy. Such strategies rely on the fact that trading volume can influence stock returns. This requires to model and forecast trading volumes and use this signal as an input to build a trading strategy.

#### Data and coding environment

Refer to the Guide to Financial Data in the Data section of the website. Once you will have designed a strategy, you can simulate its performance in a finance simulator such as Quantopian or cvxportfolio.

# 5 Crypto-currencies Price Prediction Using News and Social Networks Data

#### Description

The goal of this project is to design and implement a model that achieves good price predictions of a chosen crypto-currency. Predictions can be made using past prices information in addition to news or social networks data such as tweet sentiments and volume or google trend data.

#### Data and coding environment

Refer to the Guide to Financial Data in the Data section of the website. Historical tweets related to a specific topic such as a crypto-currency can be obtained using the following python package.

### 6 Short term Spot FX Price Prediction using Quotes from different Liquidity Providers

#### Description

The FX market is highly fragmented. There is no real notion of an order book as in equities. Each participant receives quotes from the counter-parties that they have a relationship with. At any given time, quotes from these different liquidity providers with show quotes at bid and ask that are different from each other. The LPs can also skew the mid price quote (based on their own view, or for risk management purposes.) The goal of this project is to build a hypothetical "quote book" from the data, analyze the behaviors of the the different LPs, and see if there is any information that can be detected exploiting the different views of the LPs that can predict short term price movement. Modeling techniques can include any statistical or machine learning technique. We include as references a couple of methods using reinforcement learning.

#### Data and coding environment

FX data from the integral platform are available on the class website in the Data section.

## 7 Improving on Classical Anomalies by Combining Them and perhaps adding sentiment data

### Description

Well-know market anomalies (low volatility, size, quality) exist. The goal of the project is to find alpha based on these, and to optimally combine the different signals to construct a superior portfolio. You should see if applying smarter prediction techniques (eg smarter volatility prediction for the low volatility if you can use smarter statistical/machine learning or clustering techniques either to improve on the simple anomalies or to better predict when they will work. Additionally you can include Stocktwits sentiment data.

#### Data and coding environment

Refer to the Guide to Financial Data in the Data section of the website. Once you will have designed a strategy, you can simulate its performance in a finance simulator such as Quantopian. Also, if you want to use stocktwits you'll need to use Quantopian.

### 8 Trend-Following Strategies in Futures Markets

#### Description

Trend following of futures is a classical strategy that has worked for decades. Rather than prediction, it involves quickly detecting when a trend has started, and managing when to exit a trade. The goal of this project is to replicate and improve on the basic ideas, using more advanced statistical / machine learning techniques in conjunction with exploiting correlation structures within and across asset classes.

#### Data and coding environment
