Introduction to SO and DRO

We start from considering a stochastic optimization problem as follows:

\[
\text{maximize}_{\mathbf{x} \in \mathbf{X}} \quad \mathbb{E}_{F_\xi}[h(\mathbf{x}, \xi)]
\]

(1)

where \( \mathbf{x} \) (typically called \( \beta \) in data science with minimizing a loss function) are decision variables with feasible region \( \mathbf{X} \), \( \xi \) represents random variables satisfying joint distribution \( F_\xi \).
We start from considering a stochastic optimization problem as follows:

$$\max_{x \in X} \mathbb{E}_{F_\xi}[h(x, \xi)]$$  \hspace{1cm} (1)

where $x$ (typically called $\beta$ in data science with minimizing a loss function) are decision variables with feasible region $X$, $\xi$ represents random variables satisfying joint distribution $F_\xi$.

- **Pros:** In many cases, the expected value is a good measure of performance; simply apply simple sample average (SSA) approach.

- **Cons:** One has to know the exact distribution of $\xi$ to perform the stochastic optimization. Deviant from the assumed distribution may result in sub-optimal solutions. Even know the distribution, the solution/decision is generically risky.

Goodfellow et al. [2014]
In order to overcome the lack of knowledge on the distribution, people proposed the following (static) robust optimization approach:

\[
\max_{x \in X} \min_{\xi \in \Xi} h(x, \xi)
\]  

(2)

where \(\Xi\) is the support of \(\xi\).
Robust Optimization

In order to overcome the lack of knowledge on the distribution, people proposed the following (static) robust optimization approach:

\[
\text{maximize}_{x \in X} \quad \min_{\xi \in \Xi} h(x, \xi)
\]  

(2)

where \(\Xi\) is the support of \(\xi\).

- **Pros**: Robust to any distribution; only the support of the parameters are needed.
- **Cons**: Too conservative and it ignores observed/training data information/statistics. The decision that maximizes the worst-case pay-off may perform badly in usual cases; e.g., Ben-Tal and Nemirovski [1998, 2000], etc.
Motivation for a Middle Ground

In practice, although the exact distribution of the random variables may not be known, people usually know certain observed samples or training data and other statistical information.
Motivation for a Middle Ground

- In practice, although the exact distribution of the random variables may not be known, people usually know certain observed samples or training data and other statistical information.

- Thus we could choose an intermediate approach between stochastic optimization, which has no robustness in the error of distribution; and the robust optimization, which admits vast unrealistic single-point distribution on the support set of random variables.
A solution to the above-mentioned question is to take the following Distributionally Robust Optimization/Learning (DRO) model:

$$\begin{align*}
\max_{x \in X} \min_{F_\xi \in \mathcal{D}} \mathbb{E}_{F_\xi} [h(x, \xi)]
\end{align*}$$

(3)

In DRO, we consider a set of distributions $\mathcal{D}$ and choose one to maximize the expected value for any given $x \in X$. 
A solution to the above-mentioned question is to take the following Distributionally Robust Optimization/Learning (DRO) model:

$$\max_{x \in X} \min_{F_\xi \in \mathcal{D}} \mathbb{E}_{F_\xi}[h(x, \xi)]$$  \hspace{1cm} (3)$$

In DRO, we consider a set of distributions $\mathcal{D}$ and choose one to maximize the expected value for any given $x \in X$.

When choosing $\mathcal{D}$, we need to consider the following:

- **Tractability** (fast algorithm available)
A solution to the above-mentioned question is to take the following Distributionally Robust Optimization/Learning (DRO) model:

\[
\max_{x \in X} \min_{F_\xi \in \mathcal{D}} \mathbb{E}_{F_\xi} [h(x, \xi)]
\] (3)

In DRO, we consider a set of distributions \( \mathcal{D} \) and choose one to maximize the expected value for any given \( x \in X \).

When choosing \( \mathcal{D} \), we need to consider the following:

- **Tractability** (fast algorithm available)
- **Practical (Statistical) Meanings** (utilize observed/training data)
A solution to the above-mentioned question is to take the following Distributionally Robust Optimization/Learning (DRO) model:

In DRO, we consider a set of distributions $\mathcal{D}$ and choose one to maximize the expected value for any given $x \in X$.

When choosing $\mathcal{D}$, we need to consider the following:

- **Tractability** (fast algorithm available)
- **Practical (Statistical) Meanings** (utilize observed/training data)
- **Performance** (the potential loss comparing to the benchmark cases)
Brief History of DRO

- First introduced by Scarf [1958] in the context of inventory control problem with a single random demand variable.
- Distribution set based on moments: Dupacova [1987], Prekopa [1995], Bertsimas and Popescu [2005], Delage and Y [2007,2010], etc
- Distribution set based on Likelihood/Divergences: Nilim and El Ghaoui [2005], Iyanger [2005], Wang, Glynn and Y [2012], etc
- Distribution set based on Wasserstein ambiguity set: Mohajerin Esfahani and Kuhn [2015], Blanchet, Kang, Murthy [2016], Duchi, Glynn, Namkoong [2016]
- Axiomatic motivation for DRO: Delage et al. [2017]; Ambiguous Joint Chance Constraints Under Mean and Dispersion Information: Hanasusanto et al. [2017]
Table of Contents

4. Markets for Efficient Public Good Allocation
Define

\[ D = \left\{ F_\xi \mid 
\begin{align*}
P(\xi \in \Xi) &= 1 \\
(E[\xi] - \mu_0)^T \Sigma_0^{-1}(E[\xi] - \mu_0) &\leq \gamma_1 \\
E[(\xi - \mu_0)(\xi - \mu_0)^T] &\leq \gamma_2 \Sigma_0
\end{align*}
\right\} \]

That is, the distribution set is defined based on the support, first and second order moments constraints, where \( \mu_0 \) and \( \Sigma_0 \) are sample mean vector and variance matrix.
DRO with Moment Bounds

Define

\[ \mathcal{D} = \left\{ F_\xi \mid \begin{array}{c} P(\xi \in \Xi) = 1 \\
(\mathbb{E}[\xi] - \mu_0)^T \Sigma_0^{-1} (\mathbb{E}[\xi] - \mu_0) \leq \gamma_1 \\
\mathbb{E}[(\xi - \mu_0)(\xi - \mu_0)^T] \leq \gamma_2 \Sigma_0 \end{array} \right\} \]

That is, the distribution set is defined based on the support, first and second order moments constraints, where \( \mu_0 \) and \( \Sigma_0 \) are sample mean vector and variance matrix.

Theorem

Under mild technical conditions, the DRO model can be solved to any precision \( \epsilon \) in time polynomial in \( \log(1/\epsilon) \) and the sizes of \( \mathbf{x} \) and \( \xi \).

Delage and Y [2010]
Does the construction of $D$ make a statistical sense?
Confidence Region on $F_\xi$

Does the construction of $D$ make a statistical sense?

**Theorem**

Consider

$$D(\gamma_1, \gamma_2) = \left\{ F_\xi \left| \begin{array}{l}
P(\xi \in \Xi) = 1 \\
(\mathbb{E}[\xi] - \mu_0)^T \Sigma_0^{-1} (\mathbb{E}[\xi] - \mu_0) \leq \gamma_1 \\
\mathbb{E}[((\xi - \mu_0)(\xi - \mu_0)^T] \leq \gamma_2 \Sigma_0
\end{array} \right. \right\}$$

where again $\mu_0$ and $\Sigma_0$ are point estimates from the empirical data (of size $m$) and $\Xi$ lies in a ball of radius $R$ such that $||\xi||_2 \leq R$ a.s..

Then for $\gamma_1 = O\left(\frac{R^2}{m} \log (4/\delta)\right)$ and $\gamma_2 = O\left(\frac{R^2}{\sqrt{m}} \sqrt{\log (4/\delta)}\right)$,

$$P(F_\xi \in D(\gamma_1, \gamma_2)) \geq 1 - \delta$$
Define the distribution set by the constraint on the likelihood ratio. With observed Data: $\xi_1, \xi_2, \ldots, \xi_N$, we define

$$D_N = \left\{ F_\xi \left| \begin{array}{l} P(\xi \in \Xi) = 1 \\ L(\xi, F_\xi) \geq \gamma \end{array} \right. \right\}$$

where $\gamma$ adjusts the level of robustness and $N$ represents the sample size.
DRO with Likelihood Bounds

Define the distribution set by the constraint on the likelihood ratio. With observed Data: $\xi_1, \xi_2, \ldots, \xi_N$, we define

$$D_N = \left\{ F_\xi \mid P(\xi \in \Xi) = 1, L(\xi, F_\xi) \geq \gamma \right\}$$

where $\gamma$ adjusts the level of robustness and $N$ represents the sample size.

For example, assume the support of the uncertainty is finite $\xi_1, \xi_2, \ldots, \xi_n$ and we observed $m_i$ samples on $\xi_i$. Then, $F_\xi$ has a finite discrete distribution $p_1, \ldots, p_n$ and the likelihood/entropy function

$$L(\xi, F_\xi) = \sum_{i=1}^{n} \frac{m_i}{n} \log p_i \quad \text{or} \quad L(\xi, F_\xi) = \sum_{i=1}^{n} -p_i \log(p_i \cdot \frac{n}{m_i})$$
Theory on Likelihood Bounds

The model is a convex optimization problem, and connects to many statistical theories:

- **Statistical Divergence theory**: provide a bound on KL divergence
- **Bayesian Statistics with the threshold** $\gamma$ estimated by samples: confidence level on the true distribution
- **Non-parametric Empirical Likelihood theory**: inference based on empirical likelihood by Owen
- **Asymptotic Theory of the likelihood region**
- **Possible extensions to deal with Continuous Case**

Wang, Glynn and Y [12,16]
By the Kantorovich-Rubinstein theorem, the Wasserstein distance between two distributions can be expressed as the minimum cost of moving one to the other, which is a semi-infinite transportation LP.
DRO using Wasserstein Ambiguity Set

By the Kantorovich-Rubinstein theorem, the Wasserstein distance between two distributions can be expressed as the minimum cost of moving one to the other, which is a semi-infinite transportation LP.

**Theorem**

When using the Wasserstein ambiguity set

$$\mathcal{D}_N := \{ F_\xi \mid P(\xi \in \Xi) = 1 \& d(F_\xi, \hat{F}_N) \leq \varepsilon_N \},$$

where $d(F_1, F_2)$ is the Wasserstein distance function and $N$ is the sample size, the DRO model satisfies the following properties:

- **Finite sample guarantee**: the correctness probability $\bar{P}^N$ is high
- **Asymptotic guarantee**: $\bar{P}^\infty (\lim_{N \to \infty} \hat{x}_{\varepsilon_N} = x^*) = 1$
- **Tractability**: DRO is in the same complexity class as SAA

Mohajerin Esfahani & Kuhn [15, 17], Blanchet, Kang, Murthy [16], Duchi, Glynn, Namkoong
DRO with Wasserstein Ambiguity for Logistic Regression

Let $\{(\hat{\xi}_i, \hat{\lambda}_i)\}_{i=1}^N$ be a feature-label training set i.i.d. from $P$, and consider applying logistic regression:

$$\min_x \frac{1}{N} \sum_{i=1}^N \ell(x, \hat{\xi}_i, \hat{\lambda}_i) \text{ where } \ell(x, \xi, \lambda) = \ln(1 + \exp(-\lambda x^T \xi))$$
DRO with Wasserstein Ambiguity for Logistic Regression

- Let $\{(\hat{\xi}_i, \hat{\lambda}_i)\}_{i=1}^N$ be a feature-label training set i.i.d. from $P$, and consider applying logistic regression:

$$\min_x \frac{1}{N} \sum_{i=1}^N \ell(x, \hat{\xi}_i, \hat{\lambda}_i) \text{ where } \ell(x, \xi, \lambda) = \ln(1 + \exp(-\lambda x^T \xi))$$

- DRO suggests solving $\min_x \sup_{F \in D_N} \mathbb{E}_F[\ell(x, \xi_i, \lambda_i)]$ with the Wasserstein ambiguity set.
DRO with Wasserstein Ambiguity for Logistic Regression

Let \( \{(\hat{\xi}_i, \hat{\lambda}_i)\}_{i=1}^{N} \) be a feature-label training set i.i.d. from \( P \), and consider applying logistic regression:

\[
\min_{x} \frac{1}{N} \sum_{i=1}^{N} \ell(x, \hat{\xi}_i, \hat{\lambda}_i) \text{ where } \ell(x, \xi, \lambda) = \ln(1 + \exp(-\lambda x^T \xi))
\]

DRO suggests solving \( \min_{x} \sup_{F \in \mathcal{D}_N} \mathbb{E}_F[\ell(x, \xi_i, \lambda_i)] \) with the Wasserstein ambiguity set.

When labels are considered to be error free, DRO with \( \mathcal{D}_N \) reduces to regularized logistic regression:

\[
\min_{x} \frac{1}{N} \sum_{i=1}^{N} \ell(x, \hat{\xi}_i, \hat{\lambda}_i) + \varepsilon \|x\|_*
\]

Liu at all. [2017]
Distributionally Robust Non-parametric Conditional Estimation

Conditional estimation given specific covariate values (i.e., local conditional estimation or functional estimation) is ubiquitously useful with applications in engineering, social and natural sciences. We may

$$\min_{\psi} \mathbb{E}[\| Y - \psi(X) \|^2_2],$$

where the $\min$ is taken over all infinite measurable functions.

Or it can be cast into solving a family of finite-dimensional optimization problems parametrically in $x_0$:

$$\min_{\beta} \mathbb{E}_F[\ell(Y, \beta)|X = x_0]$$

with an appropriately chosen statistical loss function $\ell$ and a response variable $Y$, given the value or observation over a covariate $X$. 
Local Conditional Estimator

But it may happen that there is no or little training data with the exact covariate $X = x_0$. Then one can consider solving a Local conditional estimation problem:

$$\min_{\beta} \mathbb{E}_F[\ell(Y, \beta)|X \in N_\gamma(x_0)]$$ (5)

where the expectation is conditioned on a neighborhood $N_\gamma(x_0)$ around $x_0$ of radius $\gamma$. Under reasonable regularity assumptions, problem (4) can be viewed as the limit of (5) as the radius $\gamma$ of the neighborhood shrinks to zero.

There are always added errors which may be due to finite sampling, noise and corrupted data. This motivates us to investigate potential strategies to robustify the local conditional estimation problem (5) under the framework of distributionally robust optimization.
We compare to DRLE $k$-nearest neighbour (KNN), Nadaraya-Watson (N-W), and Nadaraya-Epanechnikov (N-E) estimators on a digit estimation problem using the MNIST database. We executed 100 experiments where training and test sets were randomly drawn without replacement from the 60,000 training examples of this dataset.

The DRO models yield a solution with a guaranteed confidence level to the possible distributions. Specifically, the confidence region of the distributions can be constructed upon the historical data and sample distributions.
The DRO models yield a solution with a guaranteed confidence level to the possible distributions. Specifically, the confidence region of the distributions can be constructed upon the historical data and sample distributions.

The DRO models are tractable, and sometimes maintain the same computational complexity as the stochastic optimization models with known distribution.
Summary of DRO under Moment, Likelihood or Wasserstein Ambiguity Set

- The DRO models yield a solution with a guaranteed confidence level to the possible distributions. Specifically, the confidence region of the distributions can be constructed upon the historical data and sample distributions.

- The DRO models are tractable, and sometimes maintain the same computational complexity as the stochastic optimization models with known distribution.

- This approach can be applied to a wide range of problems, including inventory problems (e.g., newsvendor problem), portfolio selection problems, image reconstruction, machine learning, etc., with reported superior numerical results.

Online Linear Programming Model

The classical offline version of the above program can be formulated as a linear (integer) program as all information data would have arrived: compute \( x_t, \; t = 1, \ldots, n \) and

\[
\begin{align*}
\text{maximize}_x & \quad \sum_{t=1}^{n} r_t x_t \\
\text{subject to} & \quad \sum_{t=1}^{n} a_{it} x_t \leq b_i, \quad \forall i = 1, \ldots, m \\
& \quad x_t \in \{0, 1\} \; (0 \leq x_t \leq 1), \quad \forall t = 1, \ldots, n.
\end{align*}
\]
Online Linear Programming Model

The classical **offline** version of the above program can be formulated as a linear (integer) program as all information data would have arrived: compute $x_t$, $t = 1, \ldots, n$ and

\[
\begin{align*}
\text{maximize}_x & \quad \sum_{t=1}^n r_t x_t \\
\text{subject to} & \quad \sum_{t=1}^n a_{it} x_t \leq b_i, \quad \forall i = 1, \ldots, m \\
& \quad x_t \in \{0, 1\} \quad (0 \leq x_t \leq 1), \quad \forall t = 1, \ldots, n.
\end{align*}
\]

Now we consider the **online or streamline** and **data-driven** version of this problem:

- We only know $b$ and $n$ at the start
Online Linear Programming Model

The classical offline version of the above program can be formulated as a linear (integer) program as all information data would have arrived: compute $x_t$, $t = 1, ..., n$ and

$$\begin{align*}
\text{maximize}_x & \quad \sum_{t=1}^n r_t x_t \\
\text{subject to} & \quad \sum_{t=1}^n a_{it} x_t \leq b_i, \quad \forall i = 1, ..., m \\
& \quad x_t \in \{0, 1\} \ (0 \leq x_t \leq 1), \quad \forall t = 1, ..., n.
\end{align*}$$

Now we consider the online or streamline and data-driven version of this problem:

- We only know $b$ and $n$ at the start
- the bidder information is revealed sequentially along with the corresponding objective coefficient.
Online Linear Programming Model

The classical offline version of the above program can be formulated as a linear (integer) program as all information data would have arrived: compute $x_t$, $t = 1, \ldots, n$ and

$$\begin{align*}
\text{maximize}_x \quad & \sum_{t=1}^{n} r_t x_t \\
\text{subject to} \quad & \sum_{t=1}^{n} a_{it} x_t \leq b_i, \quad \forall i = 1, \ldots, m \\
& x_t \in \{0, 1\} \ (0 \leq x_t \leq 1), \quad \forall t = 1, \ldots, n.
\end{align*}$$

Now we consider the online or streamline and data-driven version of this problem:

- We only know $b$ and $n$ at the start
- the bidder information is revealed sequentially along with the corresponding objective coefficient.
- an irrevocable decision must be made as soon as an order arrives without observing or knowing the future data.
Main Assumptions

- $0 \leq a_{it} \leq 1$, for all $(i, t)$;
- $r_t \geq 0$ for all $t$
- The bids $(a_t, r_t)$ arrive in a random order (rather than from some iid distribution).
Model Assumptions

Main Assumptions

- $0 \leq a_{it} \leq 1$, for all $(i, t)$;
- $r_t \geq 0$ for all $t$
- The bids $(a_t, r_t)$ arrive in a random order (rather than from some iid distribution).

Denote the offline LP maximal value by $OPT(A, r)$. We call an online algorithm $A$ to be $c$-competitive if and only if

$$E_{\sigma} \left[ \sum_{t=1}^{n} r_t x_t(\sigma, A) \right] \geq c \cdot OPT(A, r),$$

where $\sigma$ is the permutation of arriving orders.

In what follows, we let

$$B = \min_{i} \{ b_i \} (> 0).$$
Main Results: Necessary and Sufficient Conditions

Theorem

For any fixed $0 < \epsilon < 1$, there is no online algorithm for solving the linear program with competitive ratio $1 - \epsilon$ if

$$B < \frac{\log(m)}{\epsilon^2}.$$
Main Results: Necessary and Sufficient Conditions

Theorem

For any fixed $0 < \epsilon < 1$, there is no online algorithm for solving the linear program with competitive ratio $1 - \epsilon$ if

$$B < \frac{\log(m)}{\epsilon^2}.$$  

Theorem

For any fixed $0 < \epsilon < 1$, there is a $1 - \epsilon$ competitive online algorithm for solving the linear program if

$$B \geq \Omega \left( \frac{m \log(n/\epsilon)}{\epsilon^2} \right).$$
Main Results: Necessary and Sufficient Conditions

**Theorem**

For any fixed $0 < \epsilon < 1$, there is no online algorithm for solving the linear program with competitive ratio $1 - \epsilon$ if

$$B < \frac{\log(m)}{\epsilon^2}.$$  

**Theorem**

For any fixed $0 < \epsilon < 1$, there is a $1 - \epsilon$ competitive online algorithm for solving the linear program if

$$B \geq \Omega \left( \frac{m \log(n/\epsilon)}{\epsilon^2} \right).$$

The problem would be easy if there are "ideal prices":

Pricing the bid: The optimal dual price vector $p^*$ of the offline LP problem can play such a role, that is $x_t^* = 1$ if $r_t > a_t^T p^*$ and $x_t^* = 0$ otherwise, yields a near-optimal solution.
Pricing the bid: The optimal dual price vector $p^*$ of the offline LP problem can play such a role, that is $x_t^* = 1$ if $r_t > a_t^T p^*$ and $x_t^* = 0$ otherwise, yields a near-optimal solution.

Based on this observation, our online algorithm works by learning a threshold price vector $\hat{p}$ and using $\hat{p}$ to price the bids.
Pricing the bid: The optimal dual price vector $p^*$ of the offline LP problem can play such a role, that is $x_t^* = 1$ if $r_t > a_t^T p^*$ and $x_t^* = 0$ otherwise, yields a near-optimal solution.

Based on this observation, our online algorithm works by learning a threshold price vector $\hat{p}$ and using $\hat{p}$ to price the bids.

One-time learning algorithm: learn the price vector once using the initial $\epsilon n$ input.
Pricing the bid: The optimal dual price vector $p^*$ of the offline LP problem can play such a role, that is $x_t^* = 1$ if $r_t > a_t^T p^*$ and $x_t^* = 0$ otherwise, yields a near-optimal solution.

Based on this observation, our online algorithm works by learning a threshold price vector $\hat{p}$ and using $\hat{p}$ to price the bids.

- **One-time learning algorithm**: learn the price vector once using the initial $\epsilon n$ input.
- **Dynamic learning algorithm**: dynamically update the prices at a carefully chosen pace.
We illustrate a simple One-Time Learning Algorithm:

- Set $x_t = 0$ for all $1 \leq t \leq \epsilon n$;
One-Time Learning Algorithm

We illustrate a simple One-Time Learning Algorithm:

- Set $x_t = 0$ for all $1 \leq t \leq \epsilon n$;
- Solve the $\epsilon$ portion of the problem

$$
\begin{align*}
\text{maximize}_x & \quad \sum_{t=1}^{\epsilon n} r_t x_t \\
\text{subject to} & \quad \sum_{t=1}^{\epsilon n} a_{it} x_t \leq (1 - \epsilon) \epsilon b_i \quad i = 1, \ldots, m \\
& \quad 0 \leq x_t \leq 1 \quad t = 1, \ldots, \epsilon n
\end{align*}
$$

and get the optimal dual solution $\hat{p}$;
One-Time Learning Algorithm

We illustrate a simple One-Time Learning Algorithm:

- Set $x_t = 0$ for all $1 \leq t \leq \epsilon n;
- Solve the $\epsilon$ portion of the problem

\[
\begin{align*}
\text{maximize}_x & \quad \sum_{t=1}^{\epsilon n} r_t x_t \\
\text{subject to} & \quad \sum_{t=1}^{\epsilon n} a_{it} x_t \leq (1 - \epsilon) \epsilon b_i \quad i = 1, \ldots, m \\
& \quad 0 \leq x_t \leq 1 \quad t = 1, \ldots, \epsilon n
\end{align*}
\]

and get the optimal dual solution $\hat{p}$;

- Determine the future allocation $x_t$ as:

\[
x_t = \begin{cases} 
0 & \text{if } r_t \leq \hat{p}^T a_t \\
1 & \text{if } r_t > \hat{p}^T a_t
\end{cases}
\]

as long as $a_{it} x_t \leq b_i - \sum_{j=1}^{t-1} a_{ij} x_j$ for all $i$; otherwise, set $x_t = 0$. 
One-Time Learning Algorithm Result

**Theorem**

For any fixed $\epsilon > 0$, the one-time learning algorithm is $(1 - \epsilon)$ competitive for solving the linear program when

$$B \geq \Omega \left( \frac{m \log(n/\epsilon)}{\epsilon^3} \right)$$

This is one $\epsilon$ worse than the optimal lower bound.
Dynamic Learning Algorithm

In the dynamic price learning algorithm, we update the price at time $\epsilon n$, $2\epsilon n$, $4\epsilon n$, ..., till $2^k \epsilon \geq 1$. 
Dynamic Learning Algorithm

In the dynamic price learning algorithm, we update the price at time $\epsilon n$, $2\epsilon n$, $4\epsilon n$, ..., till $2^k \epsilon \geq 1$.

At time $\ell \in \{\epsilon n, 2\epsilon n, ...\}$, the price vector is the optimal dual solution to the following linear program:

$$
\begin{align*}
\text{maximize}_x & \quad \sum_{t=1}^{\ell} r_t x_t \\
\text{subject to} & \quad \sum_{t=1}^{\ell} a_{it} x_t \leq (1 - h_\ell) \frac{\ell}{n} b_i \quad i = 1, ..., m \\
& \quad 0 \leq x_t \leq 1 \quad t = 1, ..., \ell
\end{align*}
$$

where

$$h_\ell = \epsilon \sqrt{n \ell};$$

and this price vector is used to determine the allocation for the next immediate period.
Geometric Pace/Grid of Price Updating

$t_1 = \varepsilon n$

$t_2 = 2\varepsilon n$

$t_3 = 4\varepsilon n$

$t_4 = 8\varepsilon n$
In the dynamic algorithm, we update the prices $\log_2 \left( \frac{1}{\epsilon} \right)$ times during the entire time horizon. One can also update prices or resolve an LP problem after every bid to achieve a lightly better competitive ratio.
In the dynamic algorithm, we update the prices $\log_2 (1/\epsilon)$ times during the entire time horizon. One can also update prices or resolve an LP problem after every bid to achieve a lightly better competitive ratio.

The numbers $h_\ell$ play an important role in improving the condition on $B$ in the main theorem. It basically balances the probability that the inventory ever gets violated and the lost of revenue due to possible left-over goods.
In the dynamic algorithm, we update the prices $\log_2 (1/\epsilon)$ times during the entire time horizon. One can also update prices or resolve an LP problem after every bid to achieve a lightly better competitive ratio.

The numbers $h_\ell$ play an important role in improving the condition on $B$ in the main theorem. It basically balances the probability that the inventory ever gets violated and the lost of revenue due to possible left-over goods.

Does the price vector converge?
Comments on Dynamic Learning Algorithm

- The numbers $h_\ell$ play an important role in improving the condition on $B$ in the main theorem. It basically balances the probability that the inventory ever gets violated and the lost of revenue due to possible left-over goods.

- Does the price vector converge?

- Can the model handle the double-market?
In the dynamic algorithm, we update the prices \( \log_2 \left( \frac{1}{\epsilon} \right) \) times during the entire time horizon. One can also update prices or resolve an LP problem after every bid to achieve a lightly better competitive ratio.

The numbers \( h_\ell \) play an important role in improving the condition on \( B \) in the main theorem. It basically balances the probability that the inventory ever gets violated and the lost of revenue due to possible left-over goods.

Does the price vector converges?

Can the model handle the double-market?

Could the online algorithm avoid solving LPs?
Recent Results: Dual Convergence I

The offline dual problem again

$$\begin{align*}
\min & \quad \sum_{i=1}^{m} b_i p_i + \sum_{j=1}^{n} y_j \\
\text{s.t.} & \quad \sum_{i=1}^{m} a_{ij} p_i + y_j \geq r_j, \quad j = 1, \ldots, n. \\
& \quad p_i, y_j \geq 0 \text{ for all } i, j.
\end{align*}$$

can be rewritten, with $d = b / n$, as:

$$\begin{align*}
\min & \quad \sum_{i=1}^{m} d_i p_i + \sum_{j=1}^{n} (r_j - \sum_{i=1}^{m} a_{ij} p_i)^+ \\
\text{s.t.} & \quad p_i \geq 0, \quad i = 1, \ldots, m.
\end{align*}$$

Here, entries of $(r_j, a_j)$ can be either positive or negative!
Recent Results: Dual Convergence II

Normalize the objective,

$$\min f_n(p) := \sum_{i=1}^{m} d_i p_i + \frac{1}{n} \sum_{j=1}^{n} (r_j - \sum_{i=1}^{m} a_{ij} p_i)^+$$

s.t. $$p_i \geq 0, \quad i = 1, \ldots, m.$$ 

Define the stochastic program

$$\min f(p) := d^\top p + \mathbb{E}_{(r,a) \sim \mathcal{P}} [(r - a^\top p)^+]$$

s.t. $$p \geq 0,$$

Observation: $$f_n(p)$$ is a sample average approximation for $$f(p)$$

The optimal dual solution $$p_n^*$$ converges to the (unique) optimal solution $$p^*$$ of the stochastic program. But at what rate?
Theorem

(Li and Y 2019) Define the binding index set $B = \{i : p_i^* = 0\}$ and the non-binding index set $N = \{i : p_i^* \neq 0\}$. Under standard stochastic assumptions (iid...), there exists a universal constant $C$ such that

$$\mathbb{P} (\|p_n^*(B) - p^*(B)\|_2 \geq \epsilon) \leq m \exp \left( -\frac{Cn\epsilon^2}{m} \right)$$

$$\mathbb{P} (\|p_n^*(N) - p^*(N)\|_2 \geq \epsilon) \leq m \exp \left( -\frac{Cn\epsilon}{m} \right)$$

for any $\epsilon > 0$, $m, n \in \mathbb{N}^+$ and $\mathcal{F} \in \Xi$. Here $p_n^*(B)$, $p^*(B)$, $p_n^*(N)$, $p^*(N)$ denote the sub-vectors corresponding to the indexes in $B$, $N$. 
Performance Metrics

“Offline” optimal solution $x^* = (x_1^*, ..., x_n^*)$ and “online” solution $x$.

$$R_n^* = \sum_{j=1}^{n} r_j x_j^* \quad \text{and} \quad R_n = \sum_{j=1}^{n} r_j x_j.$$

Objective: Minimize the worst-case gap, \textbf{Regret}, between the offline and online objective values

$$\Delta_n = \sup_{\mathcal{P} \in \Xi} \mathbb{E}_\mathcal{P} [R_n^* - R_n] \quad \text{(Stochastic Input)}$$

$$\delta_n = \sup_{\mathcal{D} \in \Xi_{\mathcal{D}}} R_n^* - \mathbb{E} [R_n] \quad \text{(Random Permutation)}$$

Also, we measure the constraint violation of the online solution

$$\nu(x) = \| (Ax - b)^+ \|_2$$

Remark: A bi-objective performance measure
Recent Results: Action-Dependent Learning

Earlier Online Algorithms

At each time $t$, compute the dual optimal solution for the problem:

$$\max_{x_j} \sum_{j=1}^{t-1} r_j x_j$$

s.t. $\sum_{j=1}^{t-1} a_{ij} x_j \leq b_i (t - 1)/n, \quad \forall i$

$$0 \leq x_j \leq 1, \quad j = 1, \ldots, t - 1$$

The algorithms are estimating $p^*$ purely using data.

Action-Dependent Learning

At each time $t$, compute the dual optimal solution for the problem:

$$\max_{x_j} \sum_{j=1}^{t-1} r_j x_j$$

s.t. $\sum_{j=1}^{t-1} a_{ij} x_j \leq \tilde{b}_i (t - 1)/n - t + 1, \quad \forall i$

$$0 \leq x_j \leq 1, \quad j = 1, \ldots, t - 1$$

where $\tilde{b}_i = b_i - \sum_{j=1}^{t-1} a_{ij} \tilde{x}_j$ – the new algorithm also considers actions already taken.
Recent Results: Action-Dependent Learning II

Provable regret performance curves with $m = 4$ when $b = o(n)$, where A1, A2, and A3 stand for Algorithm 1 (Early Dynamic Learning), Algorithm 2 (Action-Dependent), and Algorithm 3 (Using $p^*$), respectively.
Fast LP-Free Algorithm

Input: \( \mathbf{d} = \mathbf{b}/n \) and Initialize \( \mathbf{p}^1 = \mathbf{0} \)

For \( t = 1, \ldots, n \)

Set

\[
\mathbf{x}_t = \begin{cases} 
1, & r_t > \mathbf{a}_t^\top \mathbf{p}_t \\
0, & r_t \leq \mathbf{a}_t^\top \mathbf{p}_t
\end{cases}
\]

Compute

\[
\mathbf{p}_{t+1} = \mathbf{p}_t + \gamma_t (\mathbf{a}_t \mathbf{x}_t - \mathbf{d}) \\
\mathbf{p}_{t+1} = \mathbf{p}_{t+1} \vee \mathbf{0}
\]

Output: \( \mathbf{x} = (x_1, \ldots, x_n) \).

Stochastic subgradient descent for the dual equivalent form!
Performance of the Stochastic Input Model

**Theorem (Li, Sun, & Ye (2020))**

With step size $\gamma_t = 1/\sqrt{n}$, the regret and expected constraint violation of the algorithm satisfy

$$
\mathbb{E}[R_n^* - R_n] \leq O(m\sqrt{n})
$$

$$
\mathbb{E}[\nu(x)] \leq O(m\sqrt{n}).
$$

hold for all $m, n \in \mathbb{N}^+$ and distribution $\mathcal{P} \in \Xi$.

Remark: The proof utilizes the structure of the LP and largely mimics the analyses of the online gradient descent algorithm.
Theorem (Li, Sun, & Ye (2020))

With the step size $\gamma_t = \frac{1}{\sqrt{n}}$, the regret and expected constraint violation of the algorithm satisfy

$$R^*_n - \mathbb{E}[R_n] \leq O((m + \log n)\sqrt{n})$$

$$\mathbb{E}[\nu(x)] \leq O(m\sqrt{n}).$$

for all $m, n \in \mathbb{N}^+$ and $D \in \Xi_D$.

An extra $\log(n)\sqrt{n}$ in the Regret for the Permutation Input Model compared with that in the Stochastic iid Input Model. The proof builds upon the notion of Permutational Rademacher Complexity (Tolstikhin et al. 2015) which is originally used for analyzing transductive learning.
Theorem (Li, Sun, & Ye (2020))

Under the random permutation model, the regret and expected constraint violation of the two algorithms (Agrawal et al. 2014, Kesselheim et al. 2014) both satisfy

$$R^*_n - \mathbb{E}[R_n] \leq O(\sqrt{mn})$$

$$\mathbb{E}[\nu(x)] \leq O(\sqrt{mn \log n})$$

for all $m, n \in \mathbb{N}^+$ and $\mathcal{D} \in \Xi_\mathcal{D}$.

Remark: Compared with the fast algorithm, the regret and constraint violation are reduced by a factor of $\sqrt{m}$ with the price of more computation cost.

Pricing?

Artificial Currencies
How to setup “prices” for each time-period/good so that resources can be efficiently allocated while keep each individual satisfied?
The Model: Fisher’s Equilibrium Price

Buyer $i \in B$’s optimization problem for given prices $p_j, j \in G$.

$$\begin{align*}
\max & \quad u^T_i x_i := \sum_{j \in G} u_{ij} x_{ij} \\
\text{s.t.} & \quad p^T x_i := \sum_{j \in G} p_j x_{ij} \leq w_i, \\
 & \quad x_{ij} \geq 0, \quad \forall j,
\end{align*}$$

Assume that the given amount of each good is $\bar{s}_j$. The equilibrium price vector is the one that for all $j \in G$

$$\sum_{i \in B} x^*(p)_{ij} = \bar{s}_j$$

where $x^*(p)$ is a maximizer of the utility maximization problem for every buyer $i$.

The Aggregated Social Optimization Problem

\[
\begin{align*}
\text{max} & \quad \sum_{i \in B} w_i \log(u_i^T x_i) \\
\text{s.t.} & \quad \sum_{i \in B} x_{ij} = \bar{s}_j, \quad \forall j \in G \\
& \quad x_{ij} \geq 0, \quad \forall i, j,
\end{align*}
\]

**Theorem**

*(Eisenberg and Gale 1959)* Optimal dual (Lagrange) multiplier vector of equality constraints is an *equilibrium price vector*.

Proof: The optimality conditions of the social problem are *identical* to the equilibrium conditions.
The Model with Individual Physical Constraints

Buyer $i \in B$’s optimization problem for given prices $p_j, j \in G$.

\[
\begin{align*}
\text{max} \quad & u_i^T x_i := \sum_{j \in G} u_{ij} x_{ij} \\
\text{s.t.} \quad & p^T x_i := \sum_{j \in G} p_j x_{ij} \leq w_i, \\
& A_i x_i \leq b_i, \\
& x_{ij} \geq 0, \quad \forall j,
\end{align*}
\]

Could we still solve (？)

\[
\begin{align*}
\text{max} \quad & \sum_{i \in B} w_i \log(u_i^T x_i) \\
\text{s.t.} \quad & \sum_{i \in B} x_{ij} = \bar{s}_j, \quad \forall j \in G \\
& A_i x_i \leq b_i, \forall i \in B, \\
& x_{ij} \geq 0, \quad \forall i, j,
\end{align*}
\]
The Budget Adjust Mechanism

\[
\begin{align*}
\max & \quad \sum_{i \in B} (w_i + \delta_i) \log(u_i^T x_i) \\
\text{s.t.} & \quad \sum_{i \in B} x_{ij} = \bar{s}_j, \quad \forall j \in G \\
& \quad A_i x_i \leq b_i, \forall i \in B, \\
& \quad x_{ij} \geq 0, \quad \forall i, j,
\end{align*}
\]

by adding \(\delta_i \geq 0\)’s at ideal levels, which itself becomes a fixed-point computation problem.

Theorem

There is one-one correspondence of an equilibrium price vector \(p^*\) and a fixed-point solution of \(\delta^*_i\)'s, that is, \(\delta^*_i = b_i^T y_i^*\), \(\forall i\) where \(y_i^*\) is the optimal multiplier vector of constraint \(A_i x_i \leq b_i\) with input \(\delta^*_i\)'s.

Implementation: There is no need to solve the problem to the individual level but a clusters of buyers who have similar behaviors/preferences.
The Budget Adjustment Iterative Process

Adjust $\delta_{i}^{k+1} = b_{i}^{T}y_{i}^{k}$ for all $i$ iteratively where $y_{i}^{k}$ the optimal multiplier vector of constraint $A_{i}x_{i} \leq b_{i}$ with input $\delta_{i}^{k}$. 
The equilibrium price vector exist under mild technical conditions.

The problem seems able to be solved efficiently from a simple iterative procedure as described.
Summary of the Model with Physical Constraints

- The equilibrium price vector exist under mild technical conditions.
- The problem seems able to be solved efficiently from a simple iterative procedure as described.

Open questions

- Is the equilibrium price vector unique?
- Is the simple iterative procedure provably convergent?
- Is the fixed-point problem Tarski’s type?
- Is the problem in the class of PPAD or there exists a polynomial time algorithm?
