Introduction

Description of protocol

Performance of the protocol

Observations and conclusions

Characteristics of the underlying sensor network

- Dense
- Nearby nodes have correlated data
- Low energy per node
- Nodes always have data to send

Challenges in a Microsensor Network Deployment

- System lifetime
- Ease of Deployment
- Latency
- Quality

Previous work

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

- TDMA schemes
- Minimum transmission energy (MTE) routing
- Clustering approaches

Introduction

Description of protocol

Performance of the protocol

Observations and conclusions

LEACH

Has the following phases

- Cluster Head (CH) Selection
- Cluster Formation
- Steady State Phase

Figure: "Rounds" of cluster setup and data transfer

Cluster Head Formation (LEACH)

Designed mainly keeping in mind load balancing

- Node *i* elects itself with a probability *P_i*
- Expected number of cluster heads constant k
- At round *r* + 1,

$$P_{i} = \begin{cases} \frac{k}{N - k(r \mod N/k)} & \text{node } i \text{ wasn't CH in last } r \mod N/k \text{ rounds} \\ 0 & \text{otherwise} \end{cases}$$

Cluster Head Formation (LEACH) contd..

• In case of unequal energy among nodes, one may choose

$$P_i = \min\left\{\frac{E_i}{E_{total}}k, 1\right\}$$

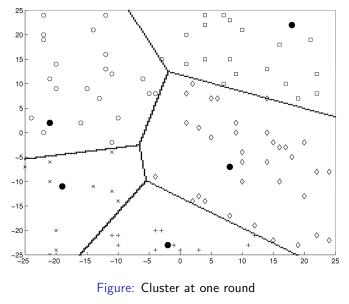

• k can be chosen based on N and the underlying energy model

Cluster Formation

- CH broadcasts an advertisement message
- Use of non persistent CSMA MAC
- Decision to join based on received signal strength

• CH sets up TDMA schedule for non CH nodes

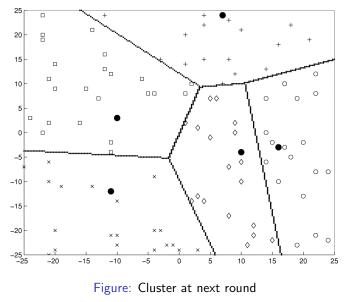

Example pictures

▶ Ξ シ۹ペ

< 🗇 🕨 🔸

Example pictures

э

- ▲ @ → - ▲ Ξ

Steady State Phase

- Power control and sleep/wake operation
- Data Aggregation at CH
- Use of DSSS to reduce inter cluster interference
- Use of CSMA to further ensure non interference

A major shortcoming

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

Each node decides locally!

LEACH-C

- BS helps in the cluster setup
- Nodes send energy and location to BS
- BS broadcasts cluster and cluster heads
- Steady state phase is the same

Analysis

- Analytic modelling is difficult
- Used network simulator ns to perform comparisons
- Comparison with MTE routing and static clustering

Details of simulated system

- 100 node system between (0,0) to (100,100)
- BS at (50,175)
- Bandwidth 1 MHz
- Each data message 500 b, header 25 b

Modelling the power consumption

• Free space models d^2 for intracluster communications

- d^4 path loss models for CH to BS communication
- Static energy and CSMA energy neglected
- Expected number of clusters per round 5

Modelling the power consumption (contd..)

• Every non CH node transmitter dissipates energy as

$$E_{tx} = \begin{cases} IE_{elec} + I\epsilon_{fs}d^2 & d < d_0\\ IE_{elec} + I\epsilon_{mp}d^4 & d \ge d_0 \end{cases}$$

Non CH receiver energy is

$$E_{rx} = IE_{elec}$$

• Every CH node dissipates energy as

$$E_{tx} = IE_{elec}(N/k - 1) + IE_{DA}N/k + IE_{elec} + I\epsilon_{mp}d^4$$

Performance metrics

- Data signals reaching the BS versus time
- Number of nodes alive versus time/data received at BS

Data signal versus time

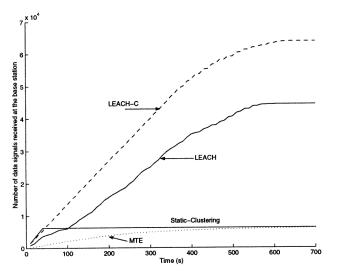

Figure: Data signals received at BS over time

Introduction

Description of protocol

Performance of the protocol

Observations and conclusions

Some critical assumptions that went into design

- Always "on"
- Every node can talk to BS
- Correlation of information in a cluster

Conclusions

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

- Clustering
- Load balancing
- Energy efficiency

Conclusions

- Clustering
- Load balancing
- Energy efficiency

All of the above make this protocol suitable in a small ad hoc microsensor network deployment

Thank you!
