

# Convex optimization examples

- multi-period processor speed scheduling
- minimum time optimal control
- grasp force optimization
- optimal broadcast transmitter power allocation
- phased-array antenna beamforming
- optimal receiver location

## Multi-period processor speed scheduling

- processor adjusts its speed  $s_t \in [s^{\min}, s^{\max}]$  in each of  $T$  time periods
- energy consumed in period  $t$  is  $\phi(s_t)$ ; total energy is  $E = \sum_{t=1}^T \phi(s_t)$
- $n$  jobs
  - job  $i$  available at  $t = A_i$ ; must finish by deadline  $t = D_i$
  - job  $i$  requires total work  $W_i \geq 0$
- $\theta_{ti} \geq 0$  is fraction of processor effort allocated to job  $i$  in period  $t$

$$\mathbf{1}^T \theta_t = 1, \quad \sum_{t=A_i}^{D_i} \theta_{ti} s_t \geq W_i$$

- choose speeds  $s_t$  and allocations  $\theta_{ti}$  to minimize total energy  $E$

## Minimum energy processor speed scheduling

- work with variables  $S_{ti} = \theta_{ti}s_t$

$$s_t = \sum_{i=1}^n S_{ti}, \quad \sum_{t=A_i}^{D_i} S_{ti} \geq W_i$$

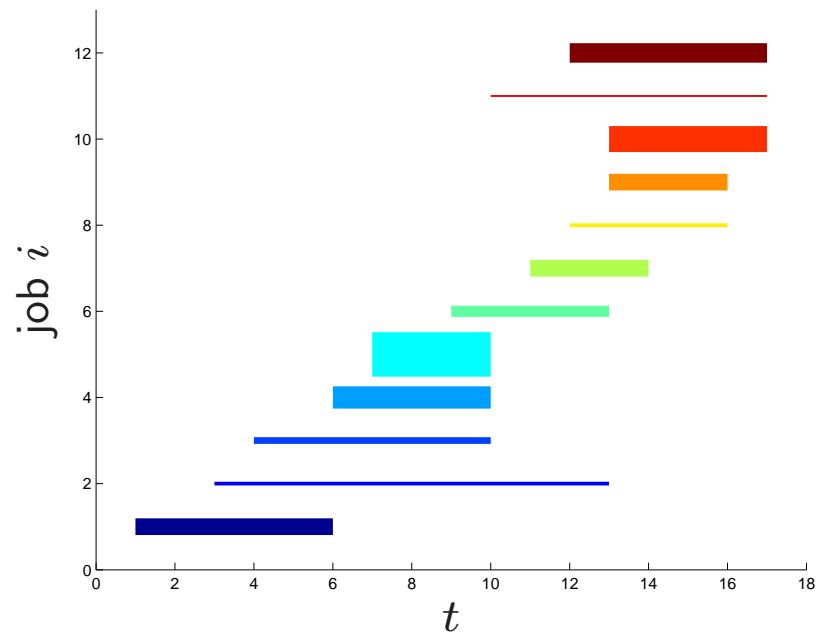

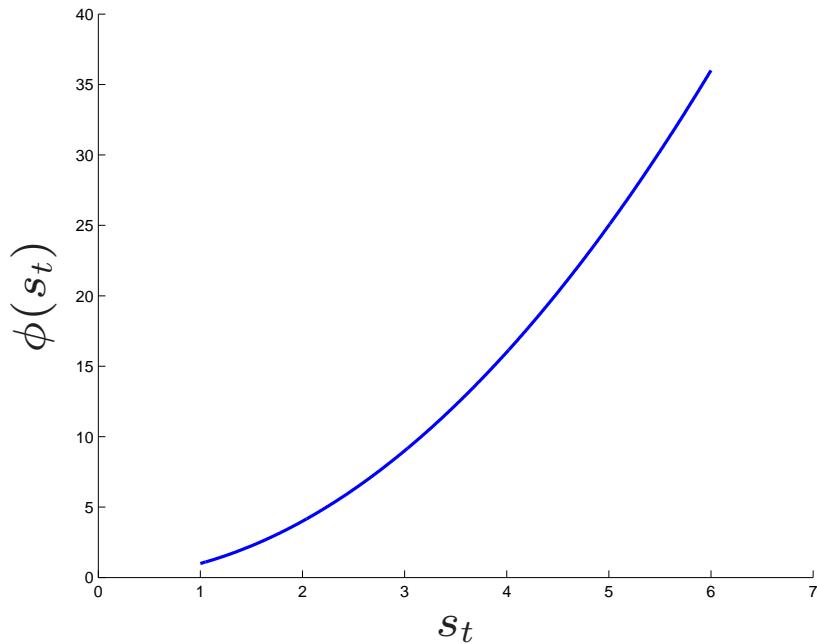

- solve convex problem

$$\begin{aligned} & \text{minimize} && E = \sum_{t=1}^T \phi(s_t) \\ & \text{subject to} && s^{\min} \leq s_t \leq s^{\max}, \quad t = 1, \dots, T \\ & && s_t = \sum_{i=1}^n S_{ti}, \quad t = 1, \dots, T \\ & && \sum_{t=A_i}^{D_i} S_{ti} \geq W_i, \quad i = 1, \dots, n \end{aligned}$$

- a convex problem when  $\phi$  is convex
- can recover  $\theta_t^*$  as  $\theta_{ti}^* = (1/s_t^*)S_{ti}^*$

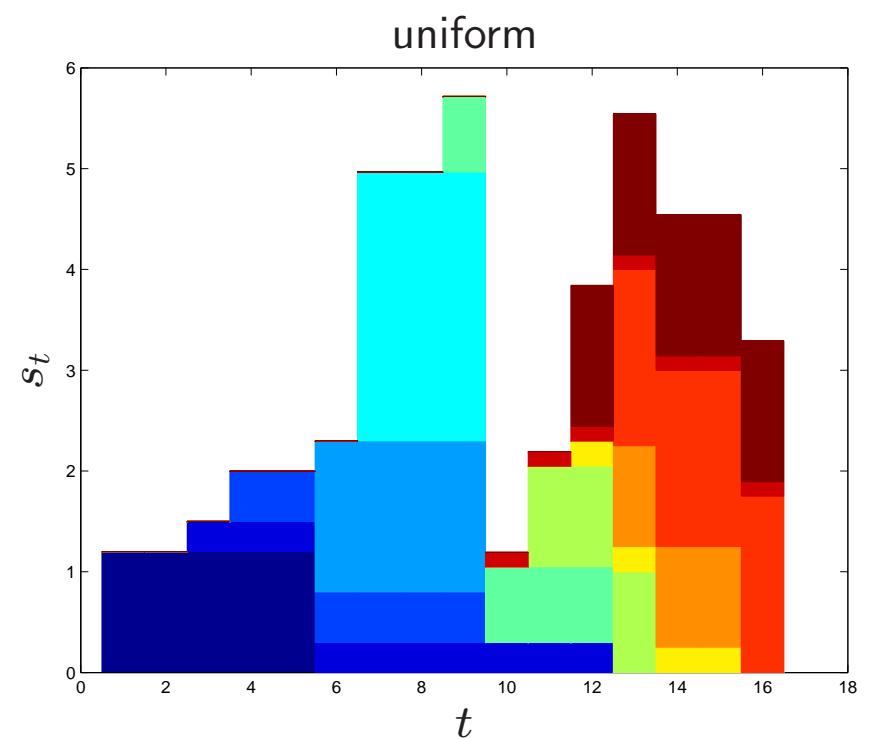

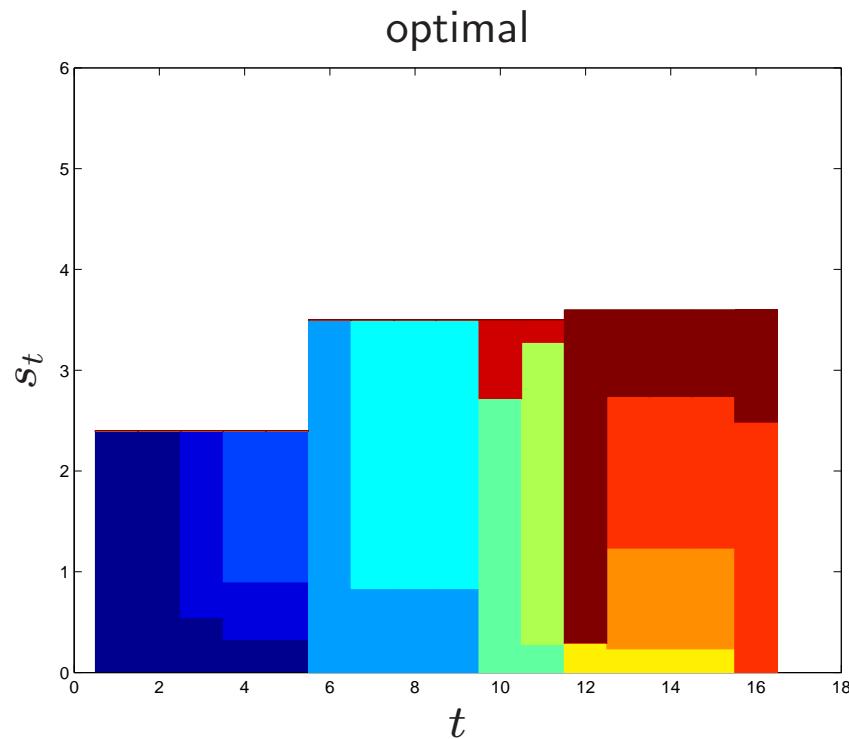

# Example

- $T = 16$  periods,  $n = 12$  jobs
- $s^{\min} = 1$ ,  $s^{\max} = 6$ ,  $\phi(s_t) = s_t^2$
- jobs shown as bars over  $[A_i, D_i]$  with area  $\propto W_i$

## Optimal and uniform schedules

- uniform schedule:  $S_{ti} = W_i/(D_i - A_i + 1)$ ; gives  $E^{\text{unif}} = 204.3$
- optimal schedule:  $S_{ti}^*$ ; gives  $E^* = 167.1$

# Minimum-time optimal control

- linear dynamical system:

$$x_{t+1} = Ax_t + Bu_t, \quad t = 0, 1, \dots, K, \quad x_0 = x^{\text{init}}$$

- inputs constraints:

$$u_{\min} \preceq u_t \preceq u_{\max}, \quad t = 0, 1, \dots, K$$

- minimum time to reach state  $x_{\text{des}}$ :

$$f(u_0, \dots, u_K) = \min \{T \mid x_t = x_{\text{des}} \text{ for } T \leq t \leq K + 1\}$$

state transfer time  $f$  is quasiconvex function of  $(u_0, \dots, u_K)$ :

$$f(u_0, u_1, \dots, u_K) \leq T$$

if and only if for all  $t = T, \dots, K + 1$

$$x_t = A^t x^{\text{init}} + A^{t-1} B u_0 + \dots + B u_{t-1} = x_{\text{des}}$$

i.e., sublevel sets are affine

**minimum-time optimal control problem:**

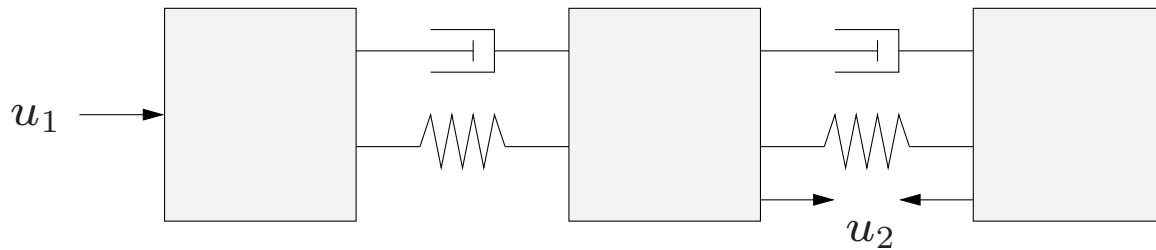

$$\text{minimize} \quad f(u_0, u_1, \dots, u_K)$$

$$\text{subject to} \quad u_{\min} \preceq u_t \preceq u_{\max}, \quad t = 0, \dots, K$$

with variables  $u_0, \dots, u_K$

a quasiconvex problem; can be solved via bisection

## Minimum-time control example

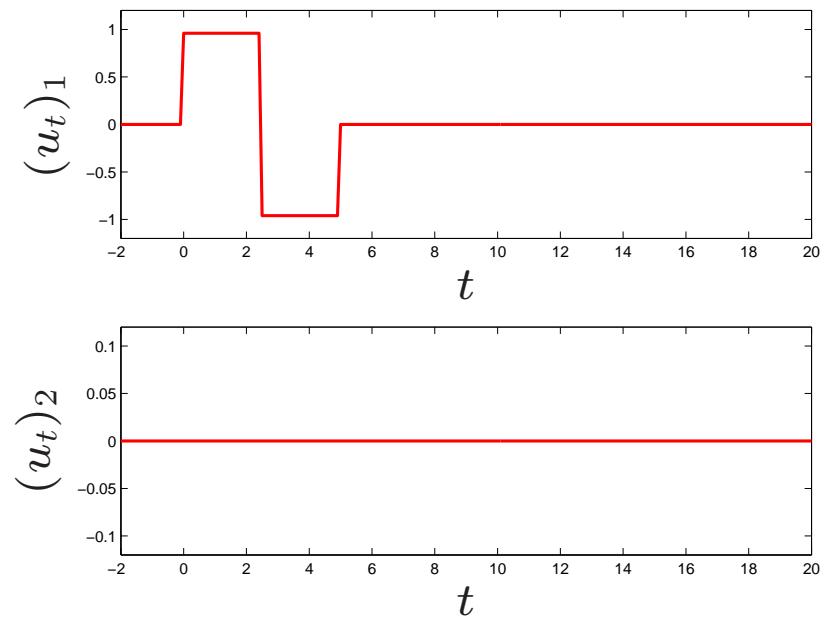

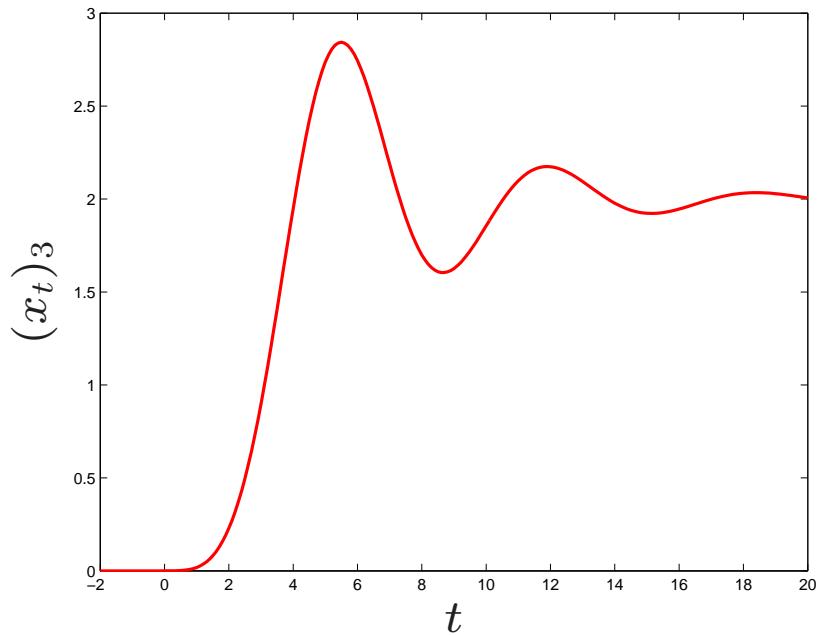

- force  $(u_t)_1$  moves object modeled as 3 masses (2 vibration modes)
- force  $(u_t)_2$  used for active vibration suppression
- goal: move object to commanded position as quickly as possible, with

$$|(u_t)_1| \leq 1, \quad |(u_t)_2| \leq 0.1, \quad t = 0, \dots, K$$

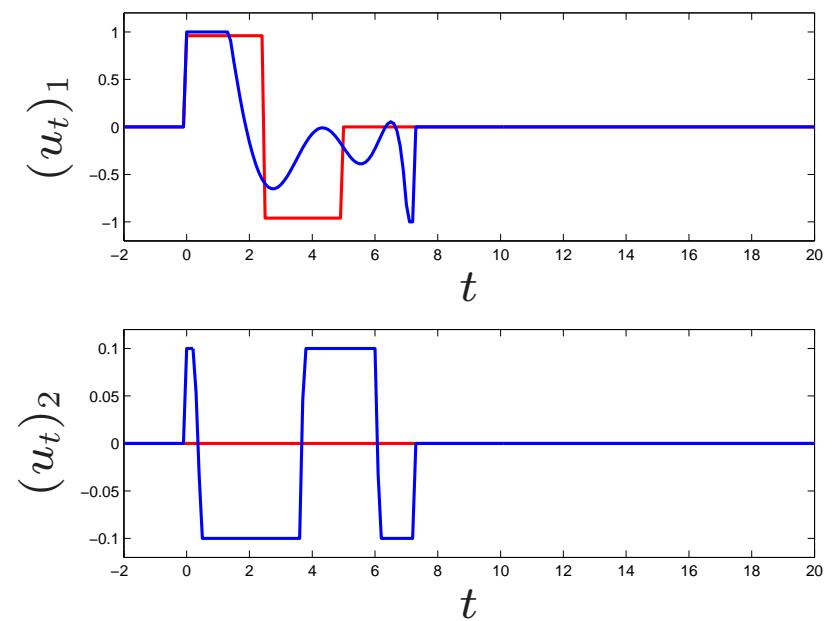

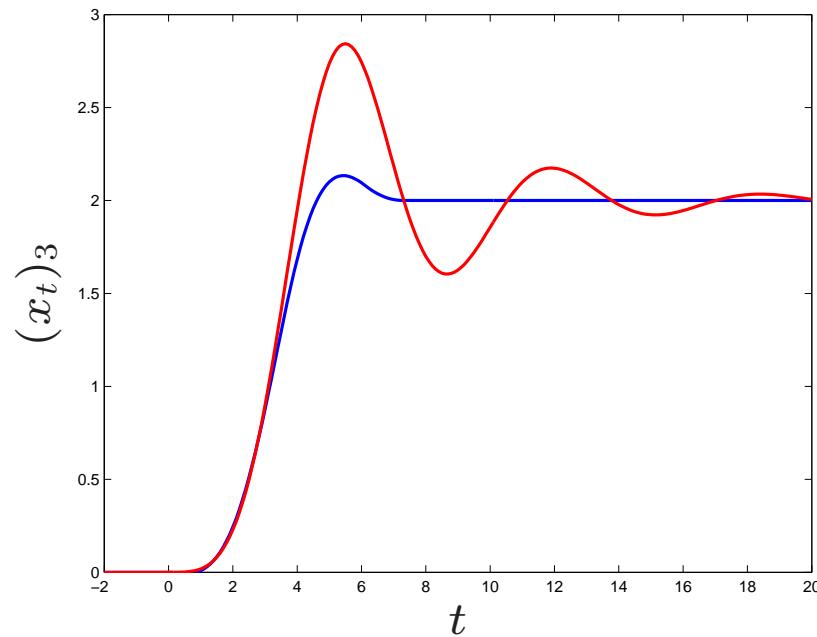

## Ignoring vibration modes

- treat object as single mass; apply only  $u_1$
- analytical ('bang-bang') solution

## With vibration modes

- no analytical solution
- a quasiconvex problem; solved using bisection

# Grasp force optimization

- choose  $K$  grasping forces on object
  - resist external wrench
  - respect friction cone constraints
  - minimize maximum grasp force
- convex problem (second-order cone program):

$$\text{minimize} \quad \max_i \|f^{(i)}\|_2$$

*max contact force*

$$\text{subject to} \quad \sum_i Q^{(i)} f^{(i)} = f^{\text{ext}}$$

*force equilibrium*

$$\sum_i p^{(i)} \times (Q^{(i)} f^{(i)}) = \tau^{\text{ext}}$$

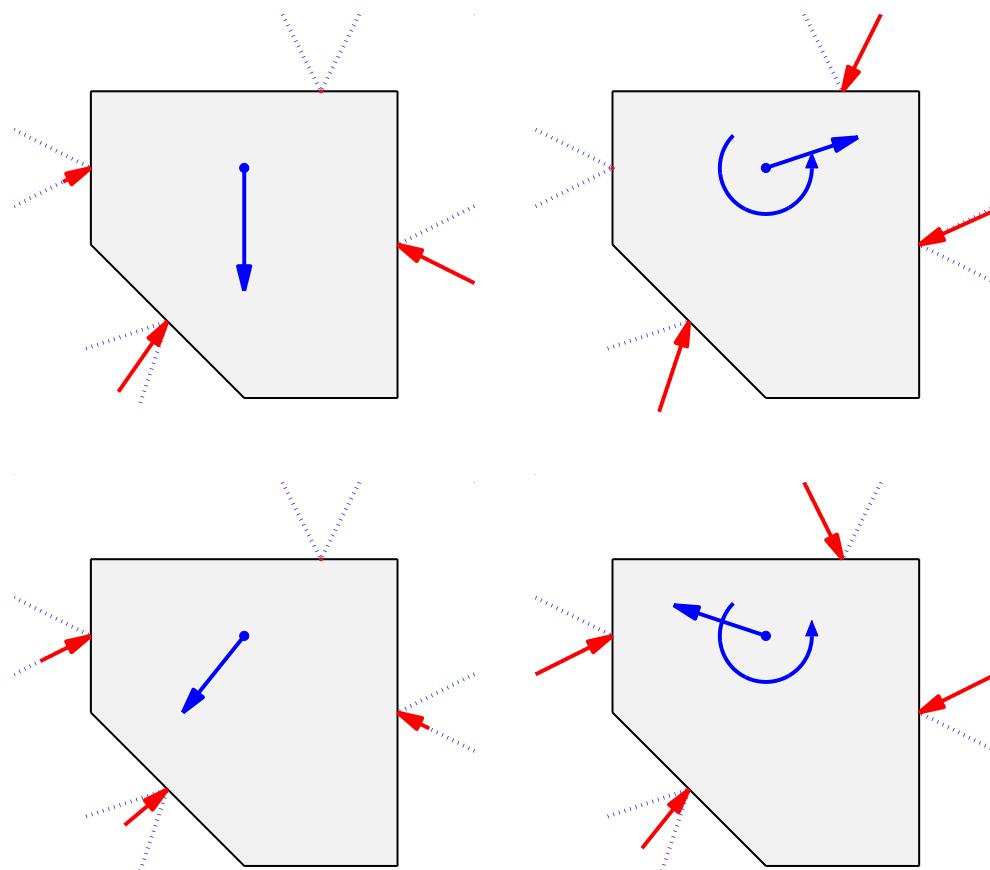

*torque equilibrium*

$$\mu_i f_3^{(i)} \geq \left( f_1^{(i)2} + f_2^{(i)2} \right)^{1/2}$$

*friction cone constraints*

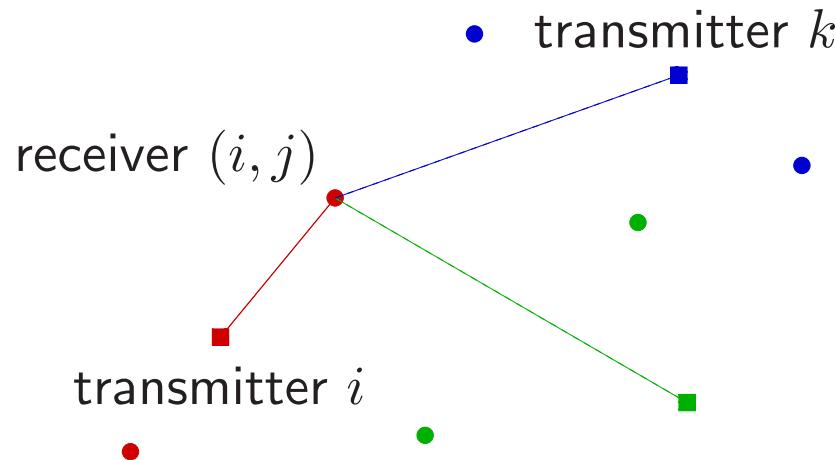

variables  $f^{(i)} \in \mathbf{R}^3$ ,  $i = 1, \dots, K$  (contact forces)

# Example

# Optimal broadcast transmitter power allocation

- $m$  transmitters,  $mn$  receivers all at same frequency
- transmitter  $i$  wants to transmit to  $n$  receivers labeled  $(i, j)$ ,  $j = 1, \dots, n$
- $A_{ijk}$  is path gain from transmitter  $k$  to receiver  $(i, j)$
- $N_{ij}$  is (self) noise power of receiver  $(i, j)$
- variables: transmitter powers  $p_k$ ,  $k = 1, \dots, m$

at receiver  $(i, j)$ :

- signal power:

$$S_{ij} = A_{iji} p_i$$

- noise plus interference power:

$$I_{ij} = \sum_{k \neq i} A_{ijk} p_k + N_{ij}$$

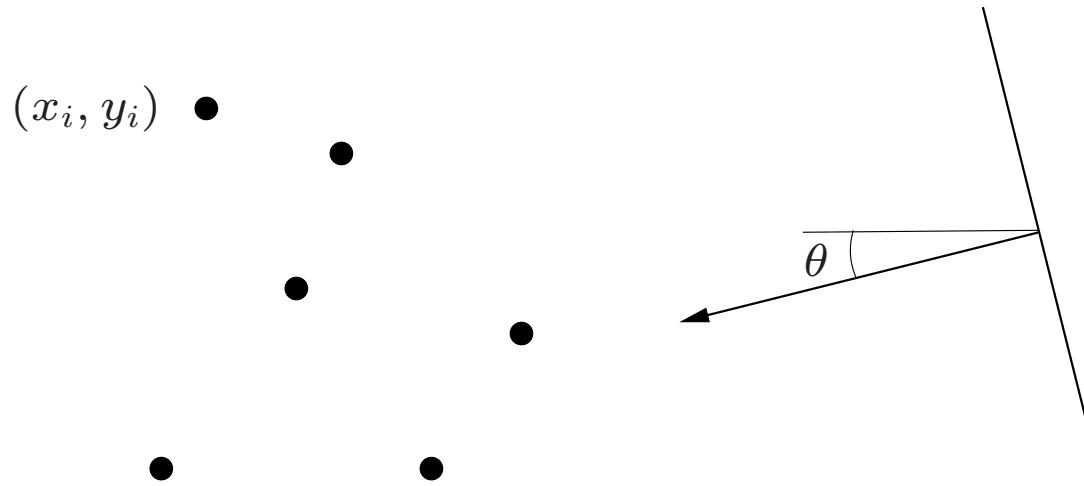

- signal to interference/noise ratio (SINR):  $S_{ij}/I_{ij}$

**problem:** choose  $p_i$  to maximize smallest SINR:

$$\begin{aligned} & \text{maximize}_{i,j} \quad \min \frac{A_{iji} p_i}{\sum_{k \neq i} A_{ijk} p_k + N_{ij}} \\ & \text{subject to} \quad 0 \leq p_i \leq p_{\max} \end{aligned}$$

. . . a (generalized) linear fractional program

## Phased-array antenna beamforming

- omnidirectional antenna elements at positions  $(x_1, y_1), \dots, (x_n, y_n)$
- unit plane wave incident from angle  $\theta$  induces in  $i$ th element a signal  $e^{j(x_i \cos \theta + y_i \sin \theta - \omega t)}$   
 $(j = \sqrt{-1}, \text{ frequency } \omega, \text{ wavelength } 2\pi)$

- demodulate to get output  $e^{j(x_i \cos \theta + y_i \sin \theta)} \in \mathbf{C}$
- linearly combine with complex weights  $w_i$ :

$$y(\theta) = \sum_{i=1}^n w_i e^{j(x_i \cos \theta + y_i \sin \theta)}$$

- $y(\theta)$  is (complex) *antenna array gain pattern*
- $|y(\theta)|$  gives sensitivity of array as function of incident angle  $\theta$
- depends on design variables  $\mathbf{Re} w$ ,  $\mathbf{Im} w$   
(called *antenna array weights* or *shading coefficients*)

**design problem:** choose  $w$  to achieve desired gain pattern

## Sidelobe level minimization

make  $|y(\theta)|$  small for  $|\theta - \theta_{\text{tar}}| > \alpha$

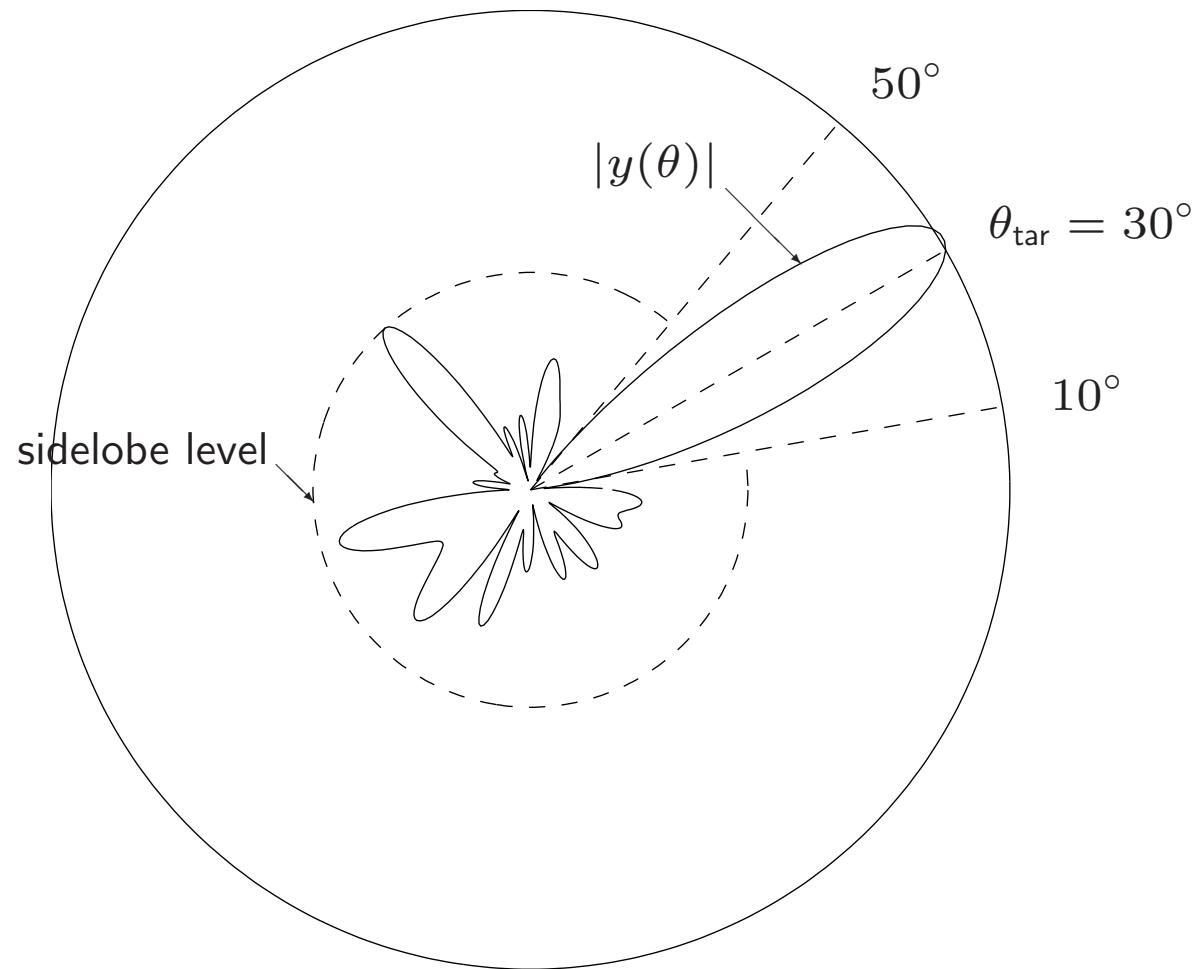

( $\theta_{\text{tar}}$ : target direction;  $2\alpha$ : beamwidth)

**via least-squares** (discretize angles)

$$\begin{aligned} &\text{minimize} && \sum_i |y(\theta_i)|^2 \\ &\text{subject to} && y(\theta_{\text{tar}}) = 1 \end{aligned}$$

(sum is over angles outside beam)

least-squares problem with two (real) linear equality constraints

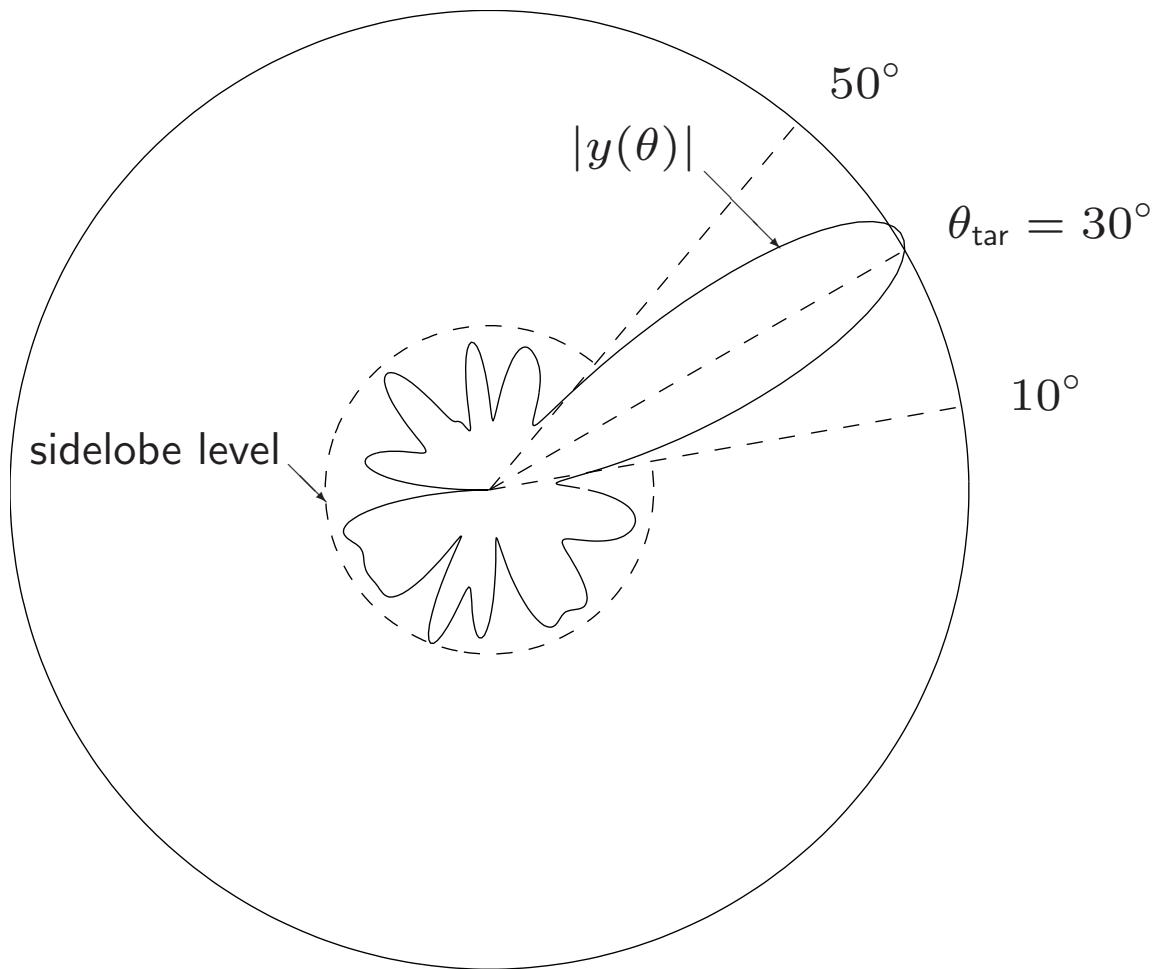

**minimize sidelobe level** (discretize angles)

$$\begin{aligned} & \text{minimize} && \max_i |y(\theta_i)| \\ & \text{subject to} && y(\theta_{\text{tar}}) = 1 \end{aligned}$$

(max over angles outside beam)

can be cast as SOCP

$$\begin{aligned} & \text{minimize} && t \\ & \text{subject to} && |y(\theta_i)| \leq t \\ & && y(\theta_{\text{tar}}) = 1 \end{aligned}$$

## Extensions

convex (& quasiconvex) extensions:

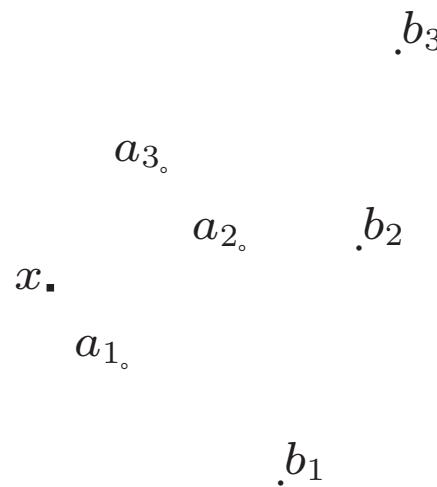

- $y(\theta_0) = 0$  (null in direction  $\theta_0$ )
- $w$  is real (amplitude only shading)
- $|w_i| \leq 1$  (attenuation only shading)
- minimize  $\sigma^2 \sum_{i=1}^n |w_i|^2$  (thermal noise power in  $y$ )
- minimize beamwidth given a maximum sidelobe level

nonconvex extension:

- maximize number of zero weights

## Optimal receiver location

- $N$  transmitter frequencies  $1, \dots, N$
- transmitters at locations  $a_i, b_i \in \mathbf{R}^2$  use frequency  $i$
- transmitters at  $a_1, a_2, \dots, a_N$  are the wanted ones
- transmitters at  $b_1, b_2, \dots, b_N$  are interfering
- receiver at position  $x \in \mathbf{R}^2$

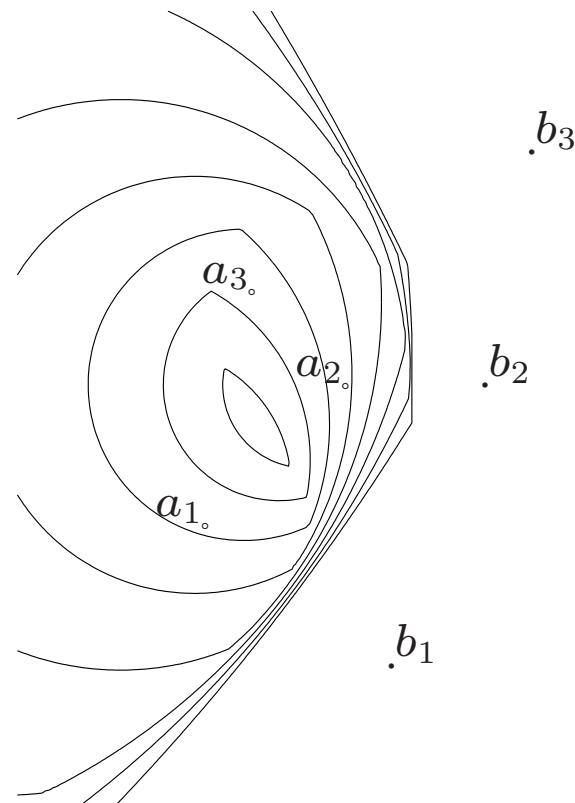

- (signal) receiver power from  $a_i$ :  $\|x - a_i\|_2^{-\alpha}$  ( $\alpha \approx 2.1$ )
- (interfering) receiver power from  $b_i$ :  $\|x - b_i\|_2^{-\alpha}$  ( $\alpha \approx 2.1$ )
- worst signal to interference ratio, over all frequencies, is

$$S/I = \min_i \frac{\|x - a_i\|_2^{-\alpha}}{\|x - b_i\|_2^{-\alpha}}$$

- what receiver location  $x$  maximizes  $S/I$ ?

$S/I$  is quasiconcave on  $\{x \mid S/I \geq 1\}$ , i.e., on

$$\{x \mid \|x - a_i\|_2 \leq \|x - b_i\|_2, i = 1, \dots, N\}$$

can use bisection; every iteration is a convex quadratic feasibility problem
